Eliason and Welty<sup>82</sup> review the records of cases of intestinal obstruction at the University of Pennsylvania Hospital in a period of ten years. Patients treated before the Miller-Abbott tube was used gave a mortality rate of 50 per cent, as compared to 11 per cent in recent years. The average age of the survivors was forty-four years, and that of those who died was fifty-nine years. The mortality in patients with cancer was 34 per cent, in strangulated femoral hernia, it was 31 per cent, and in strangulated inguinal hernia, it was 5 per cent. Excluding cancer

and strangulation obstruction in 159 consecutive cases, there was 1 death in the recent series.

Seven children with strangulated, nonreducible intussusception were treated by resection and primary anastomosis by Dennis,<sup>83</sup> with no deaths. He advocates end-to-end anastomosis with one row of silk Halsted mattress sutures, and points out that the inflammatory reaction occurring about catgut sutures may well account for edematous obstruction and failure.

Retrospect intussusception is discussed by Thorek and Lomer.<sup>84</sup> They report a case of a fifty-nine-year-old Negro who developed a gradual obstruction from an adenocarcinoma of the cecum. At operation the cecum was invaginated into the terminal ileum, which was dilated to one and a half times the size of the transverse colon. They quote Groper's<sup>85</sup> classification of retrograde intussusception as follows: jejuno gastric, enteric, cecoileal and colic.

Garlock<sup>86</sup> has analyzed 200 cases of regional ileitis treated at the Mt. Sinai Hospital, New York City. The acute phase of the disease is nearly always diagnosed and operated on as acute appendicitis. The patients do surprisingly well, and in many cases the disabling chronic phase of the disease does not follow. If remissions last for a number of years after an acute onset, the patient rarely has a recurrence. Although some patients with chronic cases do well on conservative measures and are not disabled by the disease process, the majority of them develop fever, weight loss, fistulas and abscesses. This tendency makes it justifiable to consider them as primarily a surgical problem. Ileotransverse colostomy, following a division of the ileum with closure of the distal segment, gives the best results. There was no mortality after this procedure, and only 10.5 per cent of patients developed recurrences requiring resection of the terminal ileum and right portion of the colon. Ileocolostomy in continuity not only failed to improve these patients but also made them worse. One-stage resections were associated with a mortality of 16.3 per cent and recurrences of 15.4 per cent. Two-stage resections resulted in 12 per cent mortality and 28.6 per cent recurrences. Garlock believes that the disease starts in the ileum and not in the lymphatic vessels. He calls attention to the fact that fistulas close spontaneously after they are excluded by ileotransverse colostomy.

#### THE COLON

Beck and Hopkins<sup>87</sup> report 5 cases of diverticulitis of the cecum. Four patients had acute manifestations and were operated on with the diagnosis of acute appendicitis. Two were treated by simple resection of the diverticulum, 1 by right colectomy and primary ileotransverse colostomy, and 1 by a resection of the Mikulicz type. One case was diagnosed preoperatively, and the diverticulum excised after a planned cholecystectomy.

Two cases of diverticulitis of the cecum and ascending colon are reported by Fairbank and Rob.<sup>88</sup> They discuss the difficulties in differentiating these lesions clinically from carcinoma. Both patients were treated by right hemicolectomy with recovery.

Anderson<sup>89</sup> reviews this subject and finds 91 reports of acute diverticulitis of the cecum in the surgical literature. Diverticula in the colon are found in 5.7 per cent of roentgenograms and 6.9 per cent of autopsies at the Mayo Clinic. In 700 cases of surgical diverticulitis treated there, only 9 were in the right portion of the colon. Eight case histories are given in the report. Resection of the right portion of the colon or cecum had been carried out in one third of the cases, probably because they could not be distinguished from perforated carcinoma. The preoperative diagnosis in 84 of the 91 cases reported was acute appendicitis. The operative mortality in the whole group was 6.4 per cent. Local procedures when they could be done carried less risk than bowel resection. The average age of these patients was thirty-nine years and two months. This is striking, since the more common sigmoid diverticulitis is found in a much older age group.

Pemberton et al.<sup>90</sup> have reported the results obtained in the surgical treatment of 389 patients with diverticulitis of the sigmoid colon. Two hundred and forty-five of these were treated between 1908 and 1940, with a mortality of 14.7 per cent. One hundred and forty-four were treated from 1941 to 1945, with a mortality of 4.2 per cent. The authors deduce from their experience that proximal colostomy should be done in all acute cases. They advise resection of the diseased area by the Mikulicz principle six to twelve months later. They attribute the better results obtained in the second group of patients largely to the use of sulfonamides.

Scott and Serenati<sup>91</sup> have analyzed the records of 31 patients with megacolon occurring in 250,000 admissions to the Strong Memorial Hospital, Rochester, New York. These cases are divided into four categories: neurogenic, congenital with organic obstruction, functional with obstruction, and those with extrinsic metabolic effects such as avitaminosis, malnutrition and hypothyroidism. The congenital obstructions are relieved surgically without further consideration. Conservative measures are carried out in all other cases. Parasympathetic drugs, enemas and mineral oil are given a thorough trial. Spinal anesthesia may bring about a dramatic temporary effect, and when this occurs, sympathectomy is indicated. In some cases, in which there seems to be a more lasting effect from spinal anesthesia, a continuation of conservative treatment is justified. If colectomy is done, the authors advise only a left hemicolectomy and a lateral anastomosis to produce the widest possible stoma.

Young and his associates<sup>92</sup> report 7 cases of volvulus of the cecum, which they consider to account for slightly more than 1 per cent of all cases of intestinal obstruction excluding external hernia. The authors believe that the diagnosis can often be made by a typical appearance observed in the scout roentgenogram of the abdomen. A carefully given barium enema may be necessary to confirm the diagnosis. If the lesion is early and the bowel viable, detorsion and cecostomy are advised. The fixation of the cecum by inflammatory reaction about the cecostomy prevents recurrence. Resection must be done if vascularity of the bowel has occurred. Exteriorization of the Mikulicz type is usually the safest procedure in such cases.

Volvulus of the sigmoid colon is discussed by Bruusgaard,<sup>93</sup> who states that this condition is much more common in the eastern European countries than in western Europe and the United States. He attributes this to the high vegetable diet, particularly during the war years, necessary in eastern Europe. Apparently volvulus of the sigmoid accounted for from 30 to 50 per cent of intestinal obstructions in these countries as compared to 10 per cent in the United States. Ninety-one patients with this lesion were treated in the Ullevaal Hospital, Oslo, in a ten-year period. Fifty-seven of these were over sixty years of age, whereas only 4 were under forty. The diagnosis was made by the characteristic symptoms and scout films of the abdomen. When there was fever and leukocytosis, the assumption of vascular disturbance led to immediate laparotomy and exteriorization of the bowel. If the patients had no signs or symptoms of necrosis, they were sigmoidoscoped and relieved by the passage of a soft-rubber rectal tube into the distended twisted segment of bowel. This method was successful in 123 cases. Recurrences accounted for the fact that the 91 patients had a total of 168 admissions to the hospital. If elective surgery was carried out, it was done in four stages, as follows: cecostomy, followed by exteriorization of the sigmoid with later operative closure, and finally closure of the cecostomy.

Guptill<sup>94</sup> has collected from the literature 347 cases of familial polyposis of the colon. He adds 5 cases occurring in two families that he has encountered. Very low ileorectal anastomosis with colectomy in stages is recommended. Polyps in the retained rectum must be treated by fulguration when they are found on regular examinations. The intervals of these inspections may vary from one to six months, depending on the rate at which new polyps develop. Guptill calls attention to the advisability of careful examination of all members of such families. Even those who do not have polyposis are prone to develop carcinoma of the colon on the basis of a single polyp.

The evolution of adenomas of the large intestine and their relation to carcinoma are discussed by

Helwig.<sup>95</sup> His report is based on 1460 consecutive autopsies in which 139 subjects, or nearly 10 per cent, had adenomas of the colon. Twelve of these revealed cancer on microscopical examination. He states that adenomas are true tumors and are not based on previous inflammation. The incidence was greater in white persons than in Negroes. Also, it was greater in men than in women. The incidence increased with age, and 24 per cent occurred in the eighth decade of life. The average number of adenomas found was two per subject, although 58 per cent revealed a single lesion.

Bartlett<sup>96</sup> reviews the results of treatment of 298 colostomies in an Army hospital center. He advises meticulous removal of all scar tissue of the skin, fat, fascia and bowel, followed by an accurate suture of the bowel, which is dropped free into the peritoneal cavity. Careful wound closure is then accomplished. There was only 1 fatal case in the 298 closures, which included 60 end-to-end anastomoses.

An ingenious and effective method of preparing the obstructed colon is reported by Millet.<sup>97</sup> A large rubber-tube cecostomy is done after a modification of Gibson's technic. Twenty-four hours later, a small opening is made into the anterior wall of the tube. Through this is passed a Miller-Abbott tube, which is carried by peristalsis gradually to the point of obstruction. Irrigation can then be successfully carried out through the long double-lumen tube. The bowel proximal to the obstruction can thus be thoroughly cleansed in four or five days.

Ochsner and Hines<sup>98</sup> analyzed the records of 113 consecutive cases of carcinoma of the colon coming under their care. Ninety-six of these patients, or 84.8 per cent, had resections as follows: 18 right colectomies, with no deaths, 56 left colectomies, with 2 deaths, and 48 rectosigmoid, usually by combined abdominoperineal operations, with 2 deaths. The resectability was highest in the rectosigmoid group. The authors stress the danger of recurrence when continuity is attempted in patients with low and extensive lesions.

Experience with cancer of the colon at the Massachusetts General Hospital has been brought up to date.<sup>99</sup> The resectability rate was 95 per cent in the last group of cases, as compared to 91 per cent in a former series. Primary anastomosis is done in all cases except those requiring combined procedures. An outer row of fine cotton and an inner row of fine catgut sutures are used in an open anastomosis. Obstructed cases have preliminary cecostomy, and if this is not effective, transverse colostomy is done. All patients are treated for from five to seven days with 8 gm of sulfathaladine daily before operation. Secondary wound closure is practiced. The mortality rate has been greatly reduced, largely owing to better preparation, anesthesia, blood replacement and antibiotics.

Johnston<sup>100</sup> has collected from the literature 48 cases of carcinoma of the colon occurring in children under sixteen years of age. He reports a case of colloid carcinoma of the right portion of the colon in a three-year-old child. He states that colloid carcinoma is ten times as frequent in children with cancer of the colon as it is in adults.

Gilchrist and David<sup>101</sup> have reviewed 200 cases of carcinoma of the colon and rectum operated on more than five years before. The operability rate for this period was 75 per cent, and the operative mortality was 9.5 per cent. One hundred and twenty-five patients had lymph-node metastasis. One hundred and fourteen patients, or 57 per cent, were alive and apparently well five or more years after operation. Eight patients died during the five-year period of causes other than recurrent cancer. Seventy-eight and five tenths per cent of the patients who survived for five years had no lymph-node involvement at the time of operation, whereas 44.8 per cent of those with lymph-node involvement lived five or more years. The survival rate was somewhat greater in the intraperitoneal than it was in the extraperitoneal lesions. The right portion of the colon was more favorable for cure than the left. In 35 patients with resectable extension of disease to other structures, 14 were alive and well five or more years after operation. In 11 autopsies done on patients failing to survive operation, residual positive lymph nodes were found in 4.

A ten year follow-up study on 337 patients with cancer of the colon and rectum has been presented by Colcock.<sup>102</sup> Of 103 cases of cancer of the colon, 81 (78.6 per cent) were resected. The operative mortality in this group was 16 per cent. The Mikulicz type of resection was generally used. Of 38 patients without lymph-node involvement, 5 died in the hospital, and 5 died of unrelated disease afterward. Of the 28 remaining in this group, 18 were well at the end of five years, 2 died of recurrence between the fifth and tenth years, and 16 were well at the end of ten years. Of patients who survived operation in this group, 64.3 per cent lived five years, and 57.1 per cent lived ten years. In 27 cases with extension of disease, 8 died after operation, 15 died of recurrence within five years, 1 died of recurrence after five years, and 3 were alive and well after ten years. The results on cancer of the rectum and rectosigmoid were better. There were 60 per cent five-year and 51.6 per cent ten-year survivals in cases considered favorable at the time of operation, although in the unfavorable group, there were 30.2 per cent five-year and 23.2 per cent ten-year respites. The report of Gilchrist and David<sup>101</sup> is on a slightly different basis, and this may account for the apparent variation in results in these two important contributions.

Mider<sup>103</sup> gives an interesting analysis of 726 cases of carcinoma of the colon in which 21 patients had

multiple carcinomas in the bowel, 17 cases being found at the first operation and 4 appearing later in life. Adenomatous polyps were found in 8 patients elsewhere in the colon but more usually near the site of the cancer. Seventeen per cent of the patients with single cancers had polyps as well, and 38 per cent of those having multiple malignant lesions had polyps elsewhere in the bowel.

Dunphy<sup>104</sup> has reported the results obtained in reoperation in 4 patients with recurrent carcinoma of the colon. These patients seemed to have local recurrence only, without evidence of extension to the liver and so forth. They enjoyed long respites after bloc excision of these recurrent lesions, which often involved neighboring but nonvital structures. In an attempt to explain the local rather than distant metastases, it appeared that these lesions were originally associated with inflammatory processes. Dunphy reasoned that the lymph channels leading from the area might have been previously blocked by inflammation, which led to the gradual development of remediable local recurrence.

### CASE 34111

#### PRESENTATION OF CASE

**First admission** A fifty-eight-year-old man was admitted to the hospital with progressive weakness and malaise

Four months before entry he noticed weakness and fatigue, which at first he attributed to overwork. Two months later he developed a sharp pain in the right loin, which was worse on deep inspiration. This was soon followed by cough with copious yellow sputum and a temperature of 102°F. Aspirin was given, and the right side of the chest was strapped, with slight improvement. He was then given sulfadiazine for nine days, and the temperature fell to normal but rose again after the drug was stopped, fluctuating between 99 and 102°F. There were no actual chills. Two weeks before admission he experienced a sharp severe left-upper-quadrant pain, which came on suddenly and was made worse by deep inspiration. It was accompanied by nausea, vomiting and increased fever and required morphine for relief. The pain gradually subsided over several days.

A heart murmur had been discovered on routine physical examination twenty-five years previously

and had again been noted two years before entry. There was no history of rheumatic fever.

Physical examination revealed a poorly nourished man, with pale dry skin and café-au-lait spots over the abdomen and extremities and several petechiae over the anterior surfaces of the legs. There was slight ankle edema. The heart was questionably enlarged. There were harsh systolic murmurs at the apex (Grade I) and at the base (Grade III). The aortic second sound was slightly greater than the pulmonic. There were a few moist rales at the right base. The spleen was very large, 11 cm down in the nipple line, hard and moderately tender. The liver was not definitely enlarged.

The temperature was 101°F, the pulse 88, and the respirations 22. The blood pressure was 140 systolic, 80 diastolic.

Examination of the blood disclosed a red-cell count of 3,000,000, with a hemoglobin of 11 gm, and a white-cell count of 3300, with 58 per cent neutrophils and 42 per cent lymphocytes. The serum nonprotein nitrogen was 41 mg per 100 cc, the total protein 7.2 gm, and the chloride 102 milliequiv per liter. The urine was loaded with red cells. Blood cultures were negative. An x-ray film of the chest showed partial collapse of the left upper lobe, with many areas of increased density and emphysematous blebs in the left apex. There was no infiltrative lesion. The heart and great-vessel shadows were normal. A plain film of the abdomen showed proliferative changes in the lumbar spine and a soft-tissue mass in the left side of the abdomen. An electrocardiogram was within normal limits.

The patient was started on penicillin, 500,000 units daily, later increased to 1,000,000 units and then to 2,000,000 units a day. After sixteen days of this therapy he was still having a low-grade fever and had developed an area of cellulitis at the site of the eight-day intramuscular constant penicillin drip. The drug was accordingly stopped, and blood cultures were pursued with renewed vigor without

success. Two sternal-marrow aspirations were also negative on culture. He was given four transfusions of 500 cc of blood each.

One month after admission he developed diarrhea, nausea and left abdominal pain. Examination revealed slight tenderness over the spleen and a slightly high-pitched hypoactive peristalsis, and there were new petechiae over the legs. He was then put on penicillin, 10,000,000 units intramuscularly a day in 800 cc of physiologic saline solution for four weeks with no response. During that time the white-cell count was 2500 to 8000, the hemoglobin 9.5 to 13.5 gm, the serum nonprotein nitrogen 35 to 40 mg per 100 cc, the total protein 6.1 to 7.4 gm with an albumin-globulin ratio of 0.9, the carbon dioxide 24 milliequiv and the chloride 100 milliequiv per liter, the cephalin flocculation reaction was +++ in twenty-four hours. The bromsulfalein test showed 18 per cent retention of the dye in forty-five minutes. The prothrombin time was normal. Repeated blood cultures (thirty-one in all) were still negative. The blood penicillin level was between 9.14 and 0.6 units per cubic centimeter. The urine consistently showed profuse hematuria and +++ test for albumin, the specific gravity ranging from 1.005 to 1.012. The stools were negative.

Two months after admission the patient developed ascites, and the venous pressure in the right arm was equivalent to 6 cm of saline solution. Two weeks later he had tenderness in the right calf, with some enlargement of this area, but a negative Homans's sign and absence of increased heat or dilated superficial veins. On the following day he had bilateral ankle edema, nausea and vomiting, restlessness, and pain in the anterior left portion of the chest and precordium, exaggerated by respiration. The heart rate was 100 per minute, and there was a gallop rhythm. The blood pressure was 158 systolic, 108 diastolic. An electrocardiogram showed no significant change, and a chest film revealed fluid in the right base and prominent lung roots. He was then given 0.1 gm of digitalis daily, and after a week the gallop rhythm disappeared and the edema subsided. A thoracentesis yielded 575 cc of straw-colored fluid. A biopsy of the deltoid muscle showed a small focus of degeneration with lymphocytic and monocytic infiltration. A tuberculin test gave a 2-cm area of erythema in forty-eight hours. The temperature gradually became normal. The patient was discharged three months after admission.

**Final admission** (six months later). In the interval he was taking digitalis, ferrous sulfate and components of the vitamin B complex. He felt better temporarily, and the spleen decreased in size, but later the weakness and malaise increased and he had an irregular fever. Two months previous to this admission he had an attack of left-upper-quadrant pain lasting for two days. One month later the left-upper-quadrant pain came on sharply and persisted

It was made worse by respiration, by lying on the left side and on motion and palpation of the left upper quadrant. The left shoulder and right knee were occasionally painful but not red, hot or swollen. Three weeks previous to admission he stopped the digitalis, and this did not result in increased dyspnea, cyanosis or edema. However, anorexia, malaise and fatigue became prominent symptoms, along with dry mouth, constipation and drowsiness. The urine was consistently dark.

Physical examination revealed a wasted lethargic man with fetid breath. There were numerous petechiae over the forearms, abdomen and thighs. The heart was not enlarged, there were harsh systolic murmurs at the apex and base and a high-pitched diastolic murmur in the aortic area along the left sternal border transmitted over the upper anterior portion of the chest. The aortic second sound was diminished. There were slight dullness and bronchial breathing over the left upper chest. The spleen was tender and greatly enlarged, reaching almost to the pelvis. The liver was 2 cm below the rib margin and not tender. There was no dependent edema.

The temperature was 98.6°F, and the pulse 84 and regular. The blood pressure was 110 systolic, 60 diastolic.

The white-cell count was 4000, with 86 per cent neutrophils. The serum nonprotein nitrogen was 122 mg per 100 cc, and the carbon dioxide 21.4 milliequiv per liter. The urine repeatedly showed gross hematuria and albuminuria and a specific gravity ranging from 1.008 to 1.010. A chest film showed collapse of the left upper lobe as before, but there was complete disappearance of the pleural effusion. An electrocardiogram showed a partial aorticulventricular and intraventricular block. Blood cultures were negative.

The patient continued to have severe pain in the left shoulder and left upper quadrant, and he ate and drank very little. He was given fluids parenterally but no penicillin. The temperature and respiratory rate remained normal, whereas the pulse varied between 80 and 90. The nonprotein nitrogen rose progressively to 155 mg per 100 cc, and the carbon dioxide fell to 16.6 milliequiv per liter. He became disoriented and stuporous, and the skin petechiae increased in number. Finally one month after admission, the temperature, pulse and respirations increased to 100.5, 115 and 24 respectively and he died the following morning, fourteen months after the onset of the illness.

#### DIFFERENTIAL DIAGNOSIS

**DR CONGER WILLIAMS.** In summary this patient was a fifty-eight-year-old man who died of a long febrile disease, approximately 14 months after the onset of the illness. There was a marked leukopenia, only 4000 white cells per cubic centimeter, and a mild splenomegaly, only 2 cm above the costal margin.

numerous petechiae, a persistent leukopenia and hematuria. On thinking over this very complicated problem, I believe that the possible diagnoses might be grouped under three headings. The first possibility is infection, the second, neoplasia, and the third, connective-tissue disease, such as periarteritis nodosa or lupus erythematosus.

Under the heading of infection, subacute bacterial endocarditis is the best possibility. This patient had definite heart disease, with systolic and diastolic murmurs, a persistent elevation of temperature, petechiae and successive episodes of left-upper-quadrant pain, suggesting recurrent emboli to the spleen. Another feature that fits with the diagnosis of subacute bacterial endocarditis is that of hematuria. However, I believe that macroscopic hematuria occurring so consistently during the course of subacute bacterial endocarditis is unusual. I also thought that the number of petechiae in this case was unusual. Ordinarily in subacute bacterial endocarditis, occasional petechiae are seen, when they occur in large numbers the more acute bloodstream infections or blood dyscrasias must be considered in the differential diagnosis. Another point in support of the diagnosis of subacute bacterial endocarditis was the development of the diastolic murmur along the left sternal border. Erosion of the aortic valve when it is the seat of a vegetative growth often produces such a murmur in the course of the disease. However, there is one point much against the diagnosis—the report that thirty-one blood cultures were negative. It is true that occasional cases of subacute bacterial endocarditis are seen in which a great many cultures are negative, possibly because an unusual organism, which is difficult to grow, happens to be the infecting agent. I think in this case thirty-one negative cultures are a strong argument against the diagnosis. Also, but less positively, against the diagnosis of subacute bacterial endocarditis is the lack of response to penicillin. This patient was given as much as 10,000,000 units a day over a period of one month. This does not rule out subacute bacterial endocarditis, but it does incline one a little bit against the diagnosis, especially in the absence of positive cultures.

No other diagnosis need be considered seriously under the heading of infections. Tuberculosis is a possibility in view of the long history of fluctuating temperature and the splenic enlargement and possibly the urinary findings. There was also a positive tuberculin test. However, I believed that the diagnosis of tuberculosis was very unlikely.

I think it might be a good plan to look at the x-ray films at this point.

DR. STANLEY M. WYMAN: The films show that the heart is enlarged without any particularly characteristic configuration. The collapse of the left upper lobe is seen at the left apex, but the outline is imperfectly visualized in the lateral view. The film taken to show the bronchi is not satisfactory. There

seems to be no definite obstruction in the bronchus itself. There is some calcification suggesting that the process is very old. The lung fields otherwise are clear. The film taken three weeks after this first film shows a considerable amount of fluid in the right side of the chest and to a lesser extent in the left. There is hazy density throughout the medial portions of the lung field spreading out from the hilum. This cleared completely as is seen on the film taken several months later.

A pyelogram was done. The kidney shadows are of normal contour and size and show no evidence of calcification. The enlarged spleen is very easily seen lying almost at the level of the iliac crest. The dye was excreted in poor concentration by both kidneys after considerable delay, but the outline of the urinary passages is not sufficiently satisfactory to detect any but the grossest disease. I can see no definite abnormality. There is certainly nothing to suggest an active tuberculous lesion in the lung.

DR. WILLIAMS: What about malignant tumors? Lymphoma is always a possibility when one is dealing with widespread systemic disease of this kind, and certainly it is capable of producing a persistent rise in temperature over a period of many months. Another thing that suggests the possibility is the fact that the leukopenia was rather marked and persistent. In lymphoma it is possible to have invasion of the bone marrow, with persistent leukopenia. Leukopenia, of course, is often the rule in subacute bacterial endocarditis, but it seems to me that the white-cell count was quite low, going as low as 3000 and even lower at times. Other points that suggest the possibility of lymphoma are the very persistent hematuria and albuminuria, indicating involvement of the renal tissues by a malignant process. As I said before, it is possible for the embolic phenomena in subacute bacterial endocarditis to produce this picture, but the amount and persistence of hematuria were a little bit unusual for that.

If one makes a diagnosis of malignant tumor, some of the clinical findings must be explained by assuming the presence of other disease. It seemed to me fairly definite that this patient had congestive heart failure at one time. This might be explained on the basis of long-standing aortic stenosis. Active rheumatic fever is another possibility, especially if the valvular lesions were the result of previous rheumatic infections. Recurrence of rheumatic fever is not uncommon during the course of subacute bacterial endocarditis. The possibility of myocardial involvement with a tumor process is remote. Mention was made at one point of the electrocardiographic finding of partial heart block and intraventricular block. Partial heart block is consistent with active rheumatic infection but also consistent with many other destructive lesions in the heart, as well as with coronary disease.

Metastatic carcinoma is a possibility, but I cannot imagine where the primary site would have been.

Another diagnosis to be considered is one of the "group" diseases. The possibility of periarteritis nodosa might explain the hematuria and albuminuria. The patient had a course of sulfadiazine earlier in the disease. It is well known that periarteritis nodosa may occur as a sensitivity reaction to sulfonamides, but that again is very remote. The possibility of lupus erythematosus always comes up but can hardly merit serious consideration here. I am left with two possibilities to explain the symptoms: rheumatic heart disease, with subacute bacterial endocarditis, and rheumatic heart disease with lymphoma. The thing that makes it difficult to accept subacute bacterial endocarditis is the large number of negative blood cultures, although almost everything in the history and findings suggests the diagnosis. I am inclined to accept the diagnosis of lymphoma.

DR. BENJAMIN CASTLEMAN: How do you account for the change in the murmur of a straight rheumatic basis?

DR. WILLIAMS: If the patient had active rheumatic infection he might well have had changing murmurs, especially if the infection were present over a long period. Also, a diastolic murmur could have been present before but might not have been heard.

DR. EDWARD F. BLAND: This case puzzled us for fourteen months. We went through the same line of reasoning. The fact that we were willing to treat the patient with 10,000,000 units of penicillin intramuscularly per day is an indication that we believed strongly in the diagnosis of subacute bacterial endocarditis.\* The statement in the record that he had thirty-one negative blood cultures is a modest one, because he actually had a good many more. During the second admission the whole problem was one of uremia. He was totally afebrile, and the pulse was quiet. Further blood cultures up to the time of death were negative. Actually, he died in uremia, without fever or evidence of sepsis. The hematuria continued to the end. The systolic murmur dated back many years. He had no definite rheumatic fever, and because the physical signs were those of aortic stenosis, presumably since youth, we thought of the possibility of a calcified bicuspid valve.

DR. WILLIAMS: Is it not unusual for a murmur heard twenty-five years previously to be based on a bicuspid valve? Of course another murmur, a functional murmur, may have been heard twenty-five years before.

DR. WALTER BAUER: I saw many such cases in the service.

DR. WILLIAMS: I believe that the murmurs are heard as they become more calcified in later years.

DR. BLAND: When we see frank aortic stenosis in patients under the age of twenty, we believe that a considerable number have a bicuspid valve secondarily scarred by rheumatic fever.

DR. BAUER: I thought that the diagnosis was subacute bacterial endocarditis. However, I did suggest the possibility of bistoplasmosis or toxoplasmosis but not seriously.

#### CLINICAL DIAGNOSIS

Subacute bacterial endocarditis

#### DR. WILLIAMS'S DIAGNOSES

Rheumatic heart disease, with aortic stenosis and regurgitation  
Lymphoma

#### ANATOMICAL DIAGNOSES

Subacute bacterial endocarditis  
Congenital bicuspid aortic valve  
Bronchopneumonia  
Subacute glomerulonephritis  
Healed pulmonary tuberculosis  
Infarcts of the spleen, multiple

#### PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: We have a photograph of the heart, which was slightly enlarged and showed a bicuspid aortic valve (Fig. 1). The valve flaps were covered with warty vegetations, and at one point there was a perforation through the cusp. A blood culture taken at the time of post-mortem examination was negative. However, in cultures made directly from the vegetations, alpha-hemolytic streptococcus grew out. When the organism was tested for penicillin sensitivity it was found to be extremely resistant, being inhibited only at 5 units per cubic centimeter, the highest dosage in which we tested it. The other point of major interest was the kidneys, which weighed 250 gm., were small for a man and showed scattered petechiae over the surface. Microscopical sections did not particularly suggest the focal or embolic type of nephritis usually seen in subacute bacterial endocarditis. I would classify the lesion as subacute or early chronic diffuse glomerulonephritis, which is also sometimes seen with bacterial endocarditis.

Microscopical sections of the heart valves showed extensive calcification of the vegetations, but foci of activity were still present. One rather unusual feature that I cannot remember ever having seen before was a small island of cartilage formation in one of the cusps. One sometimes sees metaplastic bone formation, but I do not happen to have seen metaplastic cartilage before in a heart valve.

The spleen weighed 650 gm. and showed three separate old infarcts. There were widespread petechiae throughout the body, skin and mucous membranes. There were a number of spots of fibrosis and one spot of fresh local infarction in the myocardium itself—unquestionably the result of very

\*This large dosage of penicillin was made possible through the courtesy of the Lederle Laboratories, New York City.

small emboli in the coronary system At the time of death the patient also had an extensive bronchopneumonia

DR BAUER At the time of autopsy was the lung consolidated?

DR MALLORY There was an old emphysema and fibrosis but no evidence of active tuberculosis

DR BAUER Was there any evidence of bronchial disease?

DR MALLORY No

DR BLAND This case illustrates one of the first patients that we have had the courage to treat so vigorously on suspicion alone In looking back, we were right, but perhaps we did not go far enough

FIGURE 1

The case illustrates the fact that older people with bacterial endocarditis are apt to run a milder course and that the disease is consequently more difficult to recognize Of course, it is easy now, but in retrospect we thought that we had controlled the disease since the patient was better when he went home after the first admission I would like to ask Dr Bauer if he thinks we should have been even more courageous and given streptomycin We were afraid of sulfadiazine because of the renal situation and because he was bordering on uremia even at the first admission

DR BAUER In retrospect, yes At the time I saw the patient I was opposed to continuing treatment because I did not believe that penicillin would be effective I had no right to make that statement because we did not know the causative organism or its penicillin sensitivity

## CASE 34112

### PRESENTATION OF CASE

*First admission* An eighty-nine-year-old woman was first admitted to the hospital with a five-day history of constipation and gradually increasing distention

The patient had been perfectly well until admission and had normal bowel habits There was no history of melena

Physical examination showed a well preserved woman in no discomfort There was marked kyphoscoliosis to the right The heart sounds were snapping, and there was a soft apical systolic murmur The abdomen was distended, tense and tympanitic, with rushed normal-pitched peristalsis in the left lower quadrant On rectal examination at the end of the finger was an irregular mass almost encircling the rectum, which felt as though it lay outside the mucosa This was nontender, and there was no blood on the examining finger

The temperature, pulse and respirations were normal

A temporary cecostomy was done the next day A week later a sigmoidoscopy was done, which showed no intrinsic tumor tissue, and a permanent double-barreled colostomy was made At this operation the surgeon noted an area of diverticulosis of the sigmoid about 10 cm long at the end of which was a tight constriction There was no involvement of the peritoneum by tumor The patient was discharged two months later

*Second admission* (five years later) In the interval she had been in fairly good health She had severe rectal tenesmus occurring in spasms several times a day, with the passage of moderate amounts of mucus and blood at times during the past year A year before readmission she passed a mass the size and shape of a duck's egg This was made up of inspissated mucus with no blood Six months later she entered another hospital complaining of chills, fever and low abdominal tenderness, but this cleared up with sulfadiazine At that time and on numerous other occasions, rectal examination showed a narrowing of the rectum, beginning 10 cm from the anus, with a large mass about it and filling the pelvis Three days before readmission she began to have severe chills and fever and lower abdominal pain On the day of admission there was abdominal distention and passage of nothing by colostomy

Physical examination revealed slight tenderness in the lower abdomen and normal-sounding peristalsis The blood pressure was 100 systolic, 60 diastolic A rectal examination was reported as follows "At one finger's length inside the anus is a large, hard, tender, slightly movable mass with a central small lumen that admits the tip of the finger There is blood on the rectal glove"

The white-cell count was 30,000, with 90 per cent neutrophils The hemoglobin was 9.7 gm, and the serum nonprotein nitrogen was 42 mg per 100 cc The urine contained albumin and many pus cells

A plain film of the abdomen showed numerous dilated loops of small and large bowel, with no gas in the distal sigmoid

A colostomy irrigation resulted in the passage of much gas

The patient was given penicillin and streptomycin but continued to have a low-grade fever, the temperature ranging from 99 to 101°F, with occasional elevations to as high as 103°F. The pulse varied from 80 to 100, and the respirations from 20 to 30. Repeated laboratory studies continued to show leukocytosis, albuminuria and pyuria. There was a rectal discharge, and irrigations yielded dark-green mucoid material. Finally she had great urinary frequency and was placed on constant bladder drainage. She died eight weeks after admission.

#### DIFFERENTIAL DIAGNOSIS

DR. JOSEPH A. HOLMES: Although it is fairly evident that this patient's two admissions were related, and it may be shown that there was only one lesion responsible for the illness at both admissions, I shall discuss each admission separately.

We have a very short and meager history of the illness prior to the first admission. Two pertinent statements were made, however — that she had been well, with normal bowel movements, and that there was no history of melena. A five-day history of constipation and gradually increasing distention leads one immediately to the assumption that there was probably frank obstruction, primarily in the large bowel, especially in the absence of any note regarding cramps, pain or vomiting.

On physical examination the findings were quite remarkable for a woman of eighty-nine years. Small-bowel obstruction appears to have been ruled out by the presence of normal-pitched peristalsis and by the absence of elevation of pulse, temperature and respirations. On rectal examination a mass was noted, although the examiner appears to be quite definite in the statement that the mass lay outside the rectal mucosa. No blood was noted on the examining finger.

We have no laboratory data on the first admission, nor is any statement made of a plain film of the abdomen. I doubt that such information would be of any assistance other than to confirm our impression that she had an acute obstruction. There is no mention of the passage of gas by rectum, so I shall assume that there was none and that there was sufficient evidence of large-bowel obstruction so that a cecostomy was done the following day. The decompression apparently relieved her sufficiently so that a week later the exploration of the abdomen could be carried out. At operation an area of diverticulosis of the sigmoid was noted, and at the lower end of this area a tight constriction was found. There was no involvement of the peritoneum or of the perirectal tissue by tumor, and no tissue was removed for biopsy.

I believe that the discussion of such cases as this at these conferences has emphasized the frequency with which carcinoma is associated with diverticulitis of the sigmoid colon. No intrinsic tumor tissue was noted on sigmoidoscopic examination, and I am

totally in agreement with the operator that in such circumstances one must assume that the entire lesion is on the basis of diverticulosis, with an area of diverticulitis at the lower end. It is probably next to impossible at operation to distinguish frank cancer associated with diverticulitis from a cicatrizing inflammatory process. I am emphasizing this because of the importance that is attached to the sigmoidoscopic examination as a preoperative procedure.

There are numerous factors involved in this case, and it is for those managing the case at the time to make the decision. Certainly the patient had lived beyond the average life span, and we know little enough about her nutrition and general condition to encourage a more radical procedure than was carried out. A permanent double-barreled colostomy was done, and she was discharged two months later.

Turning now to the second admission, five years later, we find that she had been well over this period except that she had had severe rectal tenesmus and had passed moderate amounts of mucus and blood at various times during the past year. It is obvious that there was a progressive change in the local lesion in the rectum. There was definite involvement of the mucosa, and the lumen had become smaller. There was also evidence of an inflammatory process in that she was running a low-grade fever, with occasional temperature elevations to 103°F and an elevation in the white-cell count. A fairly marked anemia was present.

Much of the evidence presented in this case leads one to believe that the lesion noted at the original operation, which persisted to death, might possibly have been that of an annular carcinoma. However, from the various studies of untreated cases of carcinoma of the colon, the life expectancy in these cases at best is not over twenty months. In the cases reported by Nathanson and Welch\* the expectancy was only fourteen months. It is necessary, then, to consider other possibilities.

Tuberculosis of the rectum is such a rare disease that I feel justified in dismissing it, particularly on the basis of the findings at the original laparotomy.

Other granulomatous lesions should be considered. Actinomycosis is a very rare disease, and such a lesion present for five years, I believe, would have caused fistulas either above or below.

There remain then few other possibilities. Malignant melanoma of the bowel, although rare, occurs frequently enough to be seriously considered in any age group. I wanted to make that diagnosis in this case, believing that the mention of the dark-green material returned with the rectal irrigations might be a clue to the nature of the lesion. This sort of material is not typical of melanoma. Again, a melanoma of the rectum would have been detected either

\*Nathanson, I. T., and Welch, C. L.: Life expectancy and incidence of malignant disease III. Carcinoma of gastro-intestinal tract. *Am. J. Cancer* 31:457-466, 1937.

on sigmoidoscopic examination or by the appearance of the bowel at the time of operation. Also, a melanoma is usually a rapidly growing lesion and if present for five years should, I believe, have become quite distinctly larger locally, with evidence of wide spread to other tissues such as the liver. No mention is made of an enlarged liver. On a similar basis, I shall exclude lymphoma of the bowel, for I believe that the lesion existed too long to have confined itself to the original locale.

This leaves me but one choice — an inflammatory process, which could well have occurred on the basis of diverticulitis alone or on the basis of diverticulosis and the presence of a foreign body that had become lodged in the area of constriction, with the subsequent development of a pelvic abscess, which gradually increased in size. We know that she had diverticulosis at the time of the first admission, and we know that diverticulitis can produce the narrowing described. I believe that the duration of the lesion over a five-year period is in favor of that diagnosis, as is the description of the terminal illness. The increased size of the local lesion can be accounted for by the formation of an abscess about it, even though the bowel had been nonfunctioning. I believe that the evidence points more toward this, with the spread of the infection eventually to involve the small intestine, causing partial obstruction to the small bowel. My diagnosis, then, remains as diverticulitis as the primary disease, with terminal abscess formation and small-bowel obstruction.

DR ERNEST M. DALAND: I first saw this patient at her home in the middle of the night. I brought her to the hospital and did a cecostomy under novocain at once. No x-ray studies were made before the second operation. The point of obstruction was obvious — high in the rectum. No tissue for biopsy could be obtained on proctoscopic examination. Only the ampulla could be inspected by the proctoscope, since obstruction was complete.

Before the exploratory operation my diagnosis was carcinoma. Afterward, because of the area of diverticulosis visualized, I believed that there was a chance that the entire process was diverticulitis. I raised the question of cancer. I told the family that I could not tell which it was but that time alone would tell.

As each of the five years passed until the next hospital admission, with very little change in the ex-

aminations, it seemed probable that the disease was diverticulitis and not cancer. During the final illness the presence of pus in the urine, the bladder irritability, the fever and the high white-cell count made me believe that the patient had a pelvic abscess from the diverticulitis and that she probably had a bladder fistula. No attempt was made to prove this, for it was believed that the treatment already instituted would not be changed.

#### CLINICAL DIAGNOSIS

Diverticulitis of sigmoid, with pelvic abscess and fistula into bladder

#### DR HOLMES'S DIAGNOSIS

Diverticulitis of sigmoid, with pelvic abscess

#### ANATOMICAL DIAGNOSES

*Adenocarcinoma of rectosigmoid (Grade II), with secondary abscess formation and extension into pelvis and uterus*

Pyometrium

Pyelonephritis, acute and chronic, left

Diverticulosis of sigmoid

#### PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN: At autopsy most of the pelvis was replaced by necrotic, friable, pale-yellow tumor, which had broken down in many areas to form green purulent abscesses. The tumor originated in the rectosigmoid and was about 8 cm long and completely annular. It had infiltrated both sides of the pelvis and extended into the uterus at the internal os to produce a pyometrium. The left ureter was surrounded by tumor in the pelvis and led to a mild pyelonephritis. Above the tumor the sigmoid contained many diverticula, but there was no evidence of infection within or around them.

The rectosigmoid tumor was a well differentiated adenocarcinoma, and I believe it might well have been present at the first operation five years before death. Tumors in elderly persons are very apt to grow slowly, invade only locally and not metastasize. Although one cannot absolutely rule out the development of the cancer on the basis of a pre-existing diverticulitis, I am more in favor of its having been present at the original admission.

## THE BOSTON HEALTH LEAGUE

UNTIL 1948 the Boston Health League had not published a report since 1940. The current report, therefore, covers considerable ground, accounting for the League's activities both during the war and in the post-war period, from 1941 to 1947.

In March, 1941, the League formed the sub-committee on health of the Committee on Public Safety to co-ordinate the city's health activities with the general defense plan. After Pearl Harbor the Health League and the Hospital Council of Boston participated actively in the Health Services Division of the Committee on Public Safety, the executive secretary of the League and the Hospital Council acting as secretary of the Division.

A committee of the League in 1940 reviewed the mental-hygiene situation in Boston agencies to bring

up to date a decade's progress since the last previous survey. In 1943 a joint committee of the Massachusetts Society for Mental Hygiene and the Health League was formed to consider mental-hygiene problems aggravated by the war situation.

In 1941 a committee was appointed to reappraise nutrition work in Boston. In 1945, at the request of the First Service Command and the First Naval District a committee on venereal disease was organized. As a result of the activities of this committee the reporting of cases of venereal disease showed a marked improvement.

Many of the regular activities of the League were maintained during the war years. It continued its work on the Group Budget Committee on Health of the Greater Boston Community Fund. It co-operated actively with the School Committee of Boston in the establishment of a unified school lunch program, under the administration of a qualified director.

In 1943 the Boston Council of Social Agencies was reorganized and became the Greater Boston Community Council. In the following spring the Boston Health League joined it, maintaining its identity, however, within the Health and Hospital Division. This has made it inevitable that metropolitan problems should come under the scrutiny of the League, although its concern remains primarily with municipal Boston.

A review of the structure and the activities of the Health League accordingly seemed indicated, and this was made in 1947. As a result of this study it seemed wise that the structure of the League should be truly representative, with a membership composed of all important agencies, voluntary and official, working in the health field, and with integration with the Hospital and Nursing Council and the Medical Social Work group.

At the annual meeting in March, 1947, member agencies agreed that the League should stand ready to point out needs in the health field, to define, allowing for flexibility, the fields of responsibility of official and voluntary agencies to carry out, in co-operation with the Research Bureau of the Community Council studies to develop new standards and techniques and to evaluate present programs.

on sigmoidoscopic examination or by the appearance of the bowel at the time of operation. sometimes have seemed, moving in grim majesty through the brick corridors of her hospital, those who knew her, knew her as a friend. She has left a deep imprint on the teaching of the art of nursing. That imprint bears the mark of unselfish devotion to a high calling, of practical idealism and of unflinching integrity.

## MASSACHUSETTS MEDICAL SOCIETY

### DEATHS

**DODD** — Isaac S. F. Dodd, M.D. of Pittsfield, died on January 29. He was in his eightieth year.  
Dr. Dodd received his degree from New York University Medical College in 1890. He was a former president of the Berkshire District Medical Society, a former vice president of the Massachusetts Medical Society and a former supervising censor. He was formerly chief of staff, House of Mercy Hospital, and was a fellow of the American College of Surgeons and American Medical Association.  
His widow, a son and a daughter survive.

**HOBERMAN** — Samuel Hoberman, M.D. of Malden died on February 18. He was in his sixty-sixth year.  
Dr. Hoberman received his degree from George Washington University School of Medicine in 1907. He was physician-in-charge at the Malden Hospital for twenty-five years and was a fellow of the American Medical Association.  
His widow, three daughters and a son survive.

**O'BRIEN** — Edward J. O'Brien, M.D. of Boston, died on February 16. He was in his sixty-first year.  
Dr. O'Brien received his degree from Tufts College Medical School in 1912. He was surgeon-in-chief at the Cambridge City Hospital, consultant to Metropolitan State Hospital, Waltham, Boston State Hospital, Somerville, Choate Memorial Hospital, Woburn, and Winchester Hospital and a gynecologist at St. Elizabeth's Hospital, Brighton, for nearly thirty years. He was a member of the New England Obstetrical and Gynecological Society and the American Urological Association and a fellow of the American College of Surgeons and the American Medical Association.  
Four sons and a daughter survive.

**OSBORNE** — Carver H. Osborne, M.D. of Brookline, died on January 3. He was in his fifty-first year.  
Dr. Osborne received his degree from Boston University School of Medicine in 1921. He was formerly a member of the staff of Truist Hospital in Fall River. He was a fellow of the American Medical Association.  
His widow and a sister survive.

**REIS** — Frederick Reis, M.D. of Jamaica Plain died on February 4. He was in his seventy-second year.  
Dr. Reis received his degree from Tufts College Medical School in 1903. He was professor of physiology and biochemistry at Tufts College Medical School. He was a member of the Massachusetts Medico-Legal Society and the American Chemical Society.  
His widow survives.

**SMITH** — Frederick G. Smith, M.D. of Somerville, died on January 9. He was in his eighty-first year.  
Dr. Smith received his degree from University of Michigan Medical School in 1893. He was a member of the staff of Somerville Hospital where he was formerly chairman of the medical board. He was a former counselor of the Massachusetts Medical Society and was a fellow of the American Medical Association.  
His widow, a daughter and a son survive.

## APPLICANTS FOR FELLOWSHIP

PUBLISHED IN ACCORDANCE WITH THE PROVISIONS OF CHAPTER V SECTION 2 OF THE BY LAWS

### BARNSTABLE DISTRICT

**BRIGGS** EDWARD F. Tufts  
Baltimore Medical College, 1906. Sponsor: Daniel H. Hiebert, Provincetown.  
**THATCHER** LYNDON H. Main Street, Dennis  
Columbia University College of Physicians and Surgeons 1934.  
Frederick Sanborn, Secretary  
Bates Avenue, Osterville

### BERKSHIRE DISTRICT

**DEWEES** BYRNE, 51 Roselyn Drive, Pittsfield  
Kansas City University of Physicians and Surgeons 1941  
Sponsor: Antonio P. Desautels 311 North Street, Pittsfield  
**GILLIGAN** THOMAS J. JR., 142 Castle Street, Great Barrington  
Columbia University College of Physicians and Surgeons 1939  
**GLUDY** HERBERT R. 26 Grace Terrace, Pittsfield  
Tufts College Medical School 1941  
**HUIDA** GERALD L., Taylor Street, Hinsdale  
Chicago Medical School, 1941. Sponsor: John C. Roe 16 South Street, Pittsfield  
**KIGHT** ROBERT P. Main Street, Stockbridge  
Northwestern University Medical School, 1933  
**WOODRUFF** CHARLOTTE S. 19 Bartlett Avenue, Pittsfield  
Long Island College of Medicine 1944  
Daniel N. Beers, Secretary  
74 North Street, Pittsfield

### BRISTOL NORTH DISTRICT

**BARNES** WILLIAM E. 1 Prospect Street, Taunton  
Tufts College Medical School 1945  
**COREN** SIMON 134 Pleasant Street, Attleboro  
Middlesex University School of Medicine 1940. Sponsor: Isadore Altman, 70 Church Street, North Attleboro  
**LOEB** ELSIE A. 142 North Washington Street, North Attleboro  
University of Munich 1936. Sponsor: James H. Brewster, 178 South Main Street, Attleboro  
**TERRANOVA** ANTHONY J. 225 South Main Street, Attleboro  
Middlesex University School of Medicine 1939. Sponsor: Frederick V. Murphy, 79 Bank Street, Attleboro  
**VELLO** BAUCE P. 137 Broadway, Taunton  
Middlesex University School of Medicine 1937. Sponsor: Myer Bloom 20 Cedar Street, Taunton.  
William E. Dawson, Secretary  
58 Winthrop Street, Taunton

### BRISTOL SOUTH DISTRICT

**JENNEY** WILLIAM L. 65 Ryan Street, New Bedford  
Yale University School of Medicine, 1945  
**MACKLER** EDWARD D. 359 Pleasant Street, New Bedford  
Tufts College Medical School 1945  
**MARTENS** THEODORE G. 218 Calvin Street, Fall River  
University of Rochester School of Medicine 1943  
**NEVES** EDMUND F. 78 Langley Street, Fall River  
Jefferson Medical College of Philadelphia 1942  
**PEREIRA** MANUEL C. 329 Foley Avenue, Somerset Center  
University of Coimbra Faculty of Medicine, Portugal 1920  
Sponsor: Warren G. Atwood 151 Rock Street, Fall River  
**POWERS** HARRY T. 633 Robeson Street, Fall River  
Cornell University Medical College 1943  
**RAPPAFORT** DAVID Circuit Avenue, Oak Bluffs  
Middlesex University School of Medicine 1942. Sponsor: Robert W. Nevin, Edgartown

SULLIVAN, THOMAS H, 78 Grant Street, Fall River  
Middlesex University School of Medicine, 1930 Sponsor  
Hilary F White, 95 Cottage Street, Fall River  
WITMER, DONALD S, 169 Belmont Street, Fall River  
College of Physicians and Surgeons, Boston, 1939 Sponsor  
H Leonard Bolen, 1524 South Main Street, Fall River  
James E Fell, *Secretary*  
181 Purchase Street, Fall River

#### ESSEX NORTH DISTRICT

BLOTNER, CARL, 248 Broadway, Lawrence  
St Louis University School of Medicine, 1933  
KAPLAN, LOUIS S, Beach Road, Salisbury  
Middlesex University School of Medicine, 1933 Sponsor  
Clarence R Hines, 39 Market Street, Amesbury  
LEE, CHARLES F, 93 Elm Street, North Andover  
Middlesex University School of Medicine, 1936 Sponsor  
John J Hartigan, 57 Jackson Street, Lawrence  
MILLER, NATHANIEL B, 222 South Main Street, Haverhill  
Middlesex University School of Medicine, 1938 Sponsor  
Paul Nettle, 282 South Main Street, Haverhill  
WHOLEY, JOHN J, 5 Birch Street, Lawrence  
Middlesex University School of Medicine, 1942 Sponsor  
Thomas V Uniacke, 46 Amesbury Street, Lawrence  
WOODMAN, ERNEST L, JR., Warwick Street, Lawrence  
Tufts College Medical School, 1939  
ZAWISLAK, JOSEPH J, 38 Avon Street, Lawrence  
Middlesex University School of Medicine, 1936 Sponsor  
John J Hartigan, 57 Jackson Street, Lawrence  
Harold R Kurth, *Secretary*  
57 Jackson Street, Lawrence

#### ESSEX SOUTH DISTRICT

MASSACHUSETTS DEPARTMENT  
OF PUBLIC HEALTHTRANSFER OF MASSACHUSETTS BLOOD  
PROGRAM TO AMERICAN RED CROSS

Since the American National Red Cross has committed itself to providing free blood and blood products to all the people of this country, the Massachusetts Department of Public Health will relinquish its blood-program activities to the Red Cross as part of the established nationwide program.

Arrangements are already underway whereby the Red Cross will gradually assume the blood-program responsibilities now carried by the Massachusetts Department of Public Health. Thus, there will be no interruption in the operation of the program. The Red Cross will take over the project on or be-

fore June 30, therefore, no funds are being provided in the budget of the Department of Public Health after that date for the collection, processing or distribution of whole blood.

The transfer of the blood program from the Department of Public Health to the American National Red Cross has the approval of the Massachusetts Medical Society, as evidenced by the following motion passed at a recent meeting of the Council:

that the Council of the Massachusetts Medical Society approve in principle the transfer of the Program for the distribution of Whole Blood and Blood Fractions from the Massachusetts Department of Public Health to the American National Red Cross with the understanding that this Society and the Massachusetts Department of Public Health will serve in an advisory and consultative capacity to the American National Red Cross on this Program.

The statewide blood program in Massachusetts has entered its third year. A summary of the activities of the program shows that 318 visits have been made to communities throughout Massachusetts. Since many of the clinics ran for more than one day, the mobile units actually collected blood on four hundred and sixty-nine days.

As of January 31, 1948, blood donations to the program amounted to 30,796 pints. It is interesting that more than a third of this blood was collected during the past six months. Factors contributing to this increase in donations are the intensified publicity campaigns, the addition of a second mobile unit and especially the growing consciousness on the part of the general public of the value of such an organized program.

The blood program has already saved Massachusetts residents thousands of dollars annually by providing blood and blood products free of charge. During the last three months of 1947, an average of over 1600 pints of whole blood was distributed per month, saving patients over \$40,000 a month for needed whole blood. In January, nearly 3000 units of gamma globulin, used for the modification of measles, was distributed to physicians in the Commonwealth. Commercially, this quantity of gamma globulin would have cost approximately \$18,000. It is estimated that the blood and blood products now available or being processed for distribution are valued at nearly half a million dollars.

The Blood Processing Laboratory of the Massachusetts Department of Public Health will continue to function as a fractionation plant. Research will be carried on to improve and develop fractionation methods. Studies in progress have already revealed several interesting discoveries. It has been found that outdated plasma can be used in the preparation of acceptable albumin and gamma globulin. Both these fractions made from overage blood plasma have successfully passed laboratory tests, and albumin has already proved thoroughly satisfactory after trial injections into human beings.

More than 21,000 pints of blood was donated to the blood program last year. This amount of blood is only a small fraction of the whole-blood needs of the Commonwealth. To meet this great demand it is necessary for all residents in communities throughout Massachusetts to participate in and support the vital program that will be operated by the American National Red Cross.

## BOOKS RECEIVED

The receipt of the following books is acknowledged and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*Studies on the Influenza A Epidemic of January-March 1941 at Gningen (Holland)*. By J. A. R. Van Bruggen, M.D., L. J. Hulmer, M.D., W. A. Hoek, J. Mulder, M.D., and L. J. Zielstra. 8 paper 79 pp. with 26 illustrations. Verhandelungen Van Het Instituut Voor Preventieve Geneeskunde VII. Leiden: Stenfert Kroese 1947. \$2.00.

In this volume of proceedings the results of a study by a group of scientists on a short term intensive epidemic of influenza A are recorded. There was a total of 117 cases of which 44 were selected for research. Thirty five of these cases were identified as influenza A virus infections by ferret inoculation and by mouse protection and complement fixation tests with patient serum. Three ferret strains were adapted to mice. These strains showed no differences in antigenic structure, but they were different from the WVS strain. Clinically severe hyperemia with small vesicles of the anterior palatal pharyngeal arches seemed to be a reliable diagnostic symptom in most cases. The authors believe that in cases of suspected influenza penicillin and the sulfonamides should be used as a prophylactic measure. During periods of malignant pandemic or interepidemic influenza large stocks of these remedies should be established in every country for the purpose of preventing pneumonia especially staphylococcal pneumonia. The report discusses the epidemiology of the Groningen outbreak and presents a clinical survey of uncomplicated cases, bacterial complications of the respiratory tract including acute tonsillitis in confirmed cases of influenza viremia and immunity reactions, the treatment and prophylaxis of bacterial lung complications. It concludes with a series of case reports, a summary and a list of references. The introduction discusses pandemic and interepidemic outbreaks and provides a list of all such epidemics in the world for the period 1933-1946. The illustrations are excellent. The lack of an index detracts from the usability of the work. The publishing is good. This monograph is recommended for all medical libraries.

*Catalogue of the Mutter Museum of the College of Physicians of Philadelphia Part I*. Compiled by Ella N. Wade. Curator. 4 paper 89 pp. Philadelphia: College of Physicians 1947.

In 1863 Dr. Thomas D. Mutter presented to the College of Physicians of Philadelphia his museum of normal and pathologic specimens. The collection was merged with one already in the possession of the College. The specimens today number over seventy three hundred and the only catalog available has been a typewritten copy in three volumes. In 1946 the idea of publishing a catalog was inaugurated and a general plan formulated and after some regrouping of specimens this first part of the projected catalog was published in the *Transactions of the College*. Further installments will be published from time to time until the work is completed. The final installment will comprise a list of donors and an index. The College is congratulated upon making available a catalog of this fine collection.

*Problems of Early Infancy* (Transactions of the First Conference March 3-4, 1947, New York City) Edited by Milton J. E. Senn, Department of Pediatrics, Cornell University Medical College 8°, paper, 70 pp New York Josiah Macy, Jr., Foundation, 1947 75¢

In this small volume the various papers read at the first conference on the problems of infancy are presented. Fourteen papers were read by psychiatrists, psychologists, social workers, pediatricians and obstetricians. The primary themes discussed were the importance of breast feeding and the rooming-in project, whereby the mother and newborn infant are kept together in one room, instead of being separated, and whereby the mother cares for her child so far as possible.

*Spezifische Typhustherapie mit einem Beitrag zur Typhuspathogenese* Von Dozent Dr. Ferdinand Nagl und Dr. Oskar Lachner 8°, paper, 63 pp, with 32 illustrations Wien Verlag Wilhelm Maudrich, 1947

This monograph discusses the vaccine treatment of typhoid fever and is based on the authors' experience in the Floridsdorf Hospital in Vienna during 1945-1946. The total admissions were 359. Various methods of treatment were used for 272 cases, and vaccine therapy for 87 cases. The total mortality was 16.4 per cent (45 cases), but only 1 patient treated with vaccine died. The material is well organized and discusses allergy and immunity, pathogenesis, bacillemia, pathological anatomy, method of vaccine therapy, statistics and the clinical aspects, illustrated with a number of temperature charts. The paper, type and printing are excellent.

## NOTICES

### GREATER BOSTON MEDICAL SOCIETY

A meeting of the Greater Boston Medical Society will be held in the auditorium of the Beth Israel Hospital on Tuesday, March 16, at 8:15 p.m. A symposium on thoracic surgery will be presented.

#### PROGRAM

Surgical Treatment of Carcinoma of the Esophagus Dr. Richard H. Sweet  
Surgical Aspects of Pulmonary Disease Dr. John W. Strieder

### HARVARD SCHOOL OF PUBLIC HEALTH

The Harvard School of Public Health announces that the Cutter Lecture on Preventive Medicine, initiated in 1912, will be held in the amphitheater of Building D, Harvard Medical School, on Monday, April 12, at 5 p.m. Dr. William N. Pildes, medical officer of health, Aygarth Rural District, Yorkshire, England, will speak on "Epidemiology in Country Practice."

The medical profession, medical and public-health students and others interested are cordially invited to attend.

## AMERICAN SOCIETY FOR THE STUDY OF STERILITY

The fourth annual national session of the American Society for the Study of Sterility will be held at the Congress Hotel, Chicago, on June 21 and 22. The two-day program will be divided into a special series of panel discussions on male infertility, with papers on female infertility and miscellaneous aspects on the second day.

The chairman is Professor Edwin G. Robertson, chairman, Department of Obstetrics and Gynecology, Queens University Faculty of Medicine, Ontario, Canada.

Additional information may be obtained from the secretary, Dr. John O. Haman, 490 Post Street, San Francisco 2, California.

## LATE REACTIONS TO METALLIC FOREIGN BODIES\*

THOMAS W. BOTSFORD, M.D.,† AND D. RICHARD FREN, M.D.‡

WEST ROXBURY, MASSACHUSETTS

**F**EW military or civilian surgeons have allowed a wound to heal around a metallic foreign body without wondering what the eventual outcome would be. Will the foreign body migrate, act as a focus of infection or cause pain, or will it become encap-

sulated and cause no symptoms? Today, many veterans have foreign bodies imbedded in various regions of the body, and in the months since the cessation of hostilities, we have had the opportunity of studying and treating a few late reactions caused by such bodies. This communication presents observations on a group of 40 patients who have

been treated at the Veterans Administration Hospital in West Roxbury, Massachusetts. The types of reactions encountered and their management are emphasized. It is of principal interest that each patient included in this study had a long and asymptomatic period between the date of recovery from the original wound and the onset of the symptoms for which he was hospitalized. Late reactions to foreign bodies are not a new phenomenon, for observations have been made concerning them after nearly all wars. However, the problem merits renewed in-

FIGURE 1. Lateral Roentgenogram of Pelvis in Case 11 Showing Position of Foreign Body on August 7, 1946

FIGURE 2. Anteroposterior Roentgenogram of Pelvis in Case 11 Showing Position of Foreign Body on August 7, 1946

ulated and cause no symptoms? Today, many veterans have foreign bodies imbedded in various regions of the body, and in the months since the cessation of hostilities, we have had the opportunity of studying and treating a few late reactions caused by such bodies. This communication presents observations on a group of 40 patients who have

terest because of its greater frequency and because of improved technic in the management of metallic foreign bodies and their complications.

When a nonabsorbable foreign body is imbedded in soft tissue it becomes gradually surrounded by a fibrous capsule.<sup>1</sup> If pathogenic micro-organisms are present and are uninhibited, an abscess and a chronically discharging sinus tract may be established, this reaction may be immediate or delayed,

and its severity will depend on the virulence of the offending organism.<sup>1</sup> Foreign bodies may remain encysted for many years without causing symptoms, as in Paschal's<sup>2</sup> patient, who had an Indian arrow-head embedded in his chest wall for sixty-one years without symptoms. This case is an exception, because as a general rule the patient who knows that he has an imbedded foreign object is more apt to have symptoms than one who is not aware of having a foreign body.<sup>3</sup> Bizarre migrations of foreign bodies occur, and Christopher<sup>4</sup> has noted many unusual

bedded foreign bodies. The information concerning these patients is summarized in Table 1. All the patients in this series were male veterans of World War II who had been wounded by enemy action. They were all in the third decade of life

FIGURE 3 *Lateral Roentgenogram of Pelvis in Case 11, Showing the Changed Position of the Foreign Body on April 9, 1947. The foreign body migrated from opposite the superior anterior edge of the fifth lumbar vertebra to below the level of the sacrum in a period of eight months.*

examples. Migration of foreign bodies usually occurs when the body is a sharp, narrow object such as a needle. However, 1 of our patients (Case 11) exhibited migration of a piece of shell fragment that was almost square (Fig 1, 2, 3, 4 and 5). Michael<sup>5</sup> has described a characteristic type of histologic foreign-body reaction to high-explosive shell fragments, but he makes no mention of the clinical application of this finding.

Between June 1 and December 31, 1946, of 1269 patients admitted to this hospital for surgery, 40\* presented symptoms referable to war wounds in which there were retained metallic foreign bodies. Of this group, we have selected 11 patients in whom the symptoms were unequivocally caused by im-

\*Since this paper was submitted for publication 23 additional patients with foreign bodies have been seen. 11 of whom have had their foreign bodies removed. Six patients had infection associated with the foreign body, and 5 had pain.

FIGURE 4 *Anteroposterior Roentgenogram of Pelvis in Case 11, Showing the Foreign Body to Have Migrated Laterally and Completely across the Right Sacroiliac Joint. This film was made on April 9, 1947. The migration occurred over a period of eight months.*

Nine patients had foreign bodies imbedded in other regions of the body than those mentioned in the table. For purposes of simplification and since the foreign bodies were not causing symptoms, they

FIGURE 5 *Photograph of the Foreign Body (Shell Fragment) Removed in Case 11.*

were not included in the table. The patients were all psychologically stable men who had been separated from the service after all their wounds had healed. The foreign bodies in all cases except 1—

a metal ring from an infantry pack — were shell fragments varying from 0.2 to 3 cm in greatest length. The foreign bodies were all located in skeletal muscle, except 1 in the liver. Six were in the lower extremity, 1 in the chest wall, 1 in the buttock, 1 in the iliopsoas muscle, and 1 in the lumbar region.

The interval between the date of healing of the initial wound and the onset of secondary symptoms varied from five to seventeen months. This fact was of especial interest, since 7 patients presented signs and symptoms of infection, and only 4 had pain alone without infection around the foreign body.

### MULTIPLE FOREIGN BODIES, WITH CELLULITIS

There were 3 patients in this group, each with multiple, minute, metallic fragments imbedded in the leg. The following case report is typical.

**CASE 3.** S. M., a 24-year-old former infantry man, was admitted to the hospital complaining of chills, fever, and swelling of the left leg of 24 hours duration. In March 1945, he had been wounded in both legs and in the abdomen by enemy action. The leg wounds had been closed secondarily and were firmly healed 2 months after the date of original trauma. Three months later he had an attack of cellulitis of the left leg which was treated by heat, elevation and parenteral ad-

TABLE 1 Pertinent Data in Patients with Embedded Foreign Bodies

CASE No.	AGE	CAUSATIVE AGENT	TYPE OF FOREIGN BODY	DATE OF INITIAL WOUND	SYMPTOM DATE LEFT LEG	ANATOMICAL LOCATION	SIGNS AND SYMPTOMS	CULTURE OF FOREIGN BODY	TREATMENT	RESULT
1	29	Shell fragments	Multiple	12-2-44	1	Left thigh and 1 in	Fever, pain and cellulitis	None performed	Penicillin and local heat	Improvement
2	24	Shell fragments	Multiple	1-11-45	1	Left thigh	Fever, pain and cellulitis	None performed	Penicillin and local heat	Improvement
3	22	Shell fragments	Multiple	3-27-45	3 at J 16, and 18	Left leg	Fever, pain and cellulitis	None performed	Penicillin and local heat	Improvement
4	26	Land mine fragments	Single	2-27-45	7	Left foot	Pain and callus formation	None performed	Removal	Cure
5	27	Shell fragments	Single	11-10-44	1	Right thigh	Draining sinus	<i>Aerobacter aerogenes</i>	Removal	Cure
6	24	Shell fragments	Single	5-10-45	12	Right shoulder	Local pain	None performed	Removal	Cure
7	28	Machine-gun bullet	Single	8-12-44	12	Right chest wall	Local pain	No organism	Removal	Cure
8	27	Shell fragments	Multiple	4-4-45	9	Liver	Pain, fever and abdominal mass	Hemolytic streptococcus and <i>Staph. albus</i>	Incision and drainage	Improvement
9	24	Shell fragments	Multiple	11-13-43	16	Left leg	Pain	None performed	Removal	Cure
10	21	Shell fragments	Multiple	11-26-44	6	Right buttock	Abscess	<i>Staph. albus</i>	Incision and drainage	Improvement
11	27	Shell fragments	Single	11-13-44	9	Right iliopsoas muscle	Abscess and sinus tract	<i>Staph. albus</i> <i>Pseudomonas morganii</i>	Incision and drainage; removal at second operation	Cure

We were able to check the Army medical records of the patients and found that the original treatment had followed the same pattern in each case. Penicillin as well as tetanus toxoid had been administered to each patient at the time of the original definitive treatment, the penicillin being continued until the wounds showed no evidence of infection. We cannot satisfactorily explain why infection suddenly occurred around a foreign body months after the wounds had healed. The pathogenic organisms at fault may have reached the site either by the blood stream or lymphatic vessels, or may have been continuously present in a dormant state. No other sites of infection elsewhere in the body, such as furuncles, infected teeth and foot infections, were found as exciting causes.

The patients are classified in three clinical groups, which are discussed separately and are as follows: multiple regional foreign bodies, with cellulitis; single or multiple foreign bodies, with abscess formation; and single foreign body, without infection but with pain.

ministration of penicillin. He was asymptomatic until the time of admission 16 months after the original injury.

Physical examination revealed a well developed and well nourished man who appeared acutely ill. The heart and lungs were normal. The abdomen was normal except for two well healed operative scars. The left leg, from the knee to the lower calf, was diffusely reddened and tender, with local edema. There was a long, irregular well healed wound over the lateral aspect of the left leg.

The temperature was 103°F. by mouth, and the pulse 100.

Examination of the blood showed a white-cell count of 8900. A roentgenogram of the left leg revealed numerous small shadows of metallic foreign bodies (Fig. 6). The diagnosis was cellulitis and multiple foreign bodies of the left leg.

The patient was treated by bed rest, elevation of the left leg and hot moist packs to the inflamed area. Penicillin was given intramuscularly in doses of 40,000 Oxford units every 3 hours. Within 48 hours, the temperature and pulse had subsided to normal and there was rapid improvement in the area of cellulitis. The treatment was continued for 7 days and the patient was discharged asymptomatic, on the 9th hospital day. At that time the leg appeared grossly normal except for the scars previously noted. Two months after discharge he was readmitted with a recurrence of the local cellulitis process. He was treated in the same manner, being hospitalized for 8 days. Again the presenting signs and symptoms cleared, and he has been symptom free for 4 months.

None of the foreign bodies were removed because of their minute size and great number, but the patient responded rapidly to local treatment and penicillin as did 2 patients with similar foreign bodies (Cases 1 and 2). These patients represent a problem in that the foreign bodies are too numerous to remove and yet act as foci for occasional explosive infections. Between attacks there has been no

FIGURE 6 Anteroposterior and Lateral Roentgenograms of Left Leg in Case 3, Showing Multiple Foreign Bodies. These were associated with recurrent bouts of cellulitis.

swelling of the leg or evidence of chronic infection as far as the patients could tell. We could find no lesions on the feet that might have been a portal of entry for pathogenic organisms, although that is a likely explanation for this type of clinical course. Undoubtedly, with multiple foreign bodies such as these, considerable scar tissue is present, as well as interference with the local flow of lymph so that any micro-organism entering the leg tends to localize in the damaged region. No bacteriologic studies were made in Case 1 since we did not feel justified in opening an area of cellulitis.

#### SINGLE OR MULTIPLE FOREIGN BODIES, WITH ABSCESS FORMATION

There were 5 patients who had localized infection caused by a foreign body. A typical case is the following:

CASE 8 M M S, a 27-year-old former infantryman, was admitted to the hospital on May 29, 1946, complaining of pain in the right upper quadrant, and of vomiting of 1 week's duration. On April 4, 1945, he had suffered a penetrating wound of the epigastrium and lacerations of the left lobe of the liver, right dome of the diaphragm, transverse mesocolon, stomach and jejunum. The wounds had been sutured, and at operation a shell fragment had been found in the jejunum and removed. The patient had been discharged from the service in August and had been asymptomatic for 9 months. He had spent no time in the tropics or the South.

Physical examination revealed a moderately obese man who appeared acutely ill. A firm, tender mass, measuring 20 by 20 cm, was located about half in the right upper quadrant and half in the epigastrium from the left upper quadrant. The remainder of the physical examination was negative.

The temperature was 101.4° F by mouth, the pulse 88, and the respirations 20.

Examination of the blood disclosed a white-cell count of 15,000, and urinalyses were normal. A plain film of the abdomen showed several small shadows consistent with metallic

FIGURE 7 Anteroposterior Roentgenogram of the Upper Abdomen in Case 4, Showing Two Foreign Bodies in the Region of the Left Lobe of the Liver. (The Other Radio-Opaque Shadows Represent Silver Hemostatic Clips.)

fragments in the region of the left lobe of the liver. The diagnosis was pyogenic liver abscess caused by foreign bodies.

The initial treatment consisted of bed rest, local heat to the abdomen and penicillin (30,000 Oxford units intramuscularly) every 3 hours. Two weeks after entry a large abscess of the left lobe of the liver was drained through an incision in the left upper quadrant. Cultures of the pus revealed hemolytic streptococci and *Staphylococcus albus*. No amebae were present either in the pus or in the stools. After drainage of the abscess, the temperature returned promptly to normal. The penicillin, however, was continued for 3 weeks.

He was discharged improved on July 13 but returned 11 days later with a recurrence of the liver abscess. X-ray films at that time showed that instead of five foreign bodies, there were only two (Fig 7). Drainage was again established, and penicillin again administered. The wound was allowed to close very slowly so that no pocket could develop, and at the end of 11 weeks the patient was discharged. Nine months later he was asymptomatic and without signs of active infection. No foreign bodies were removed at either of these operative procedures. It is probable that several of the small foreign bodies were extruded with the pus that was drained.

In this case the location of the foreign bodies in the liver made their management complicated because of technical difficulties. Even with a Berman locator, these small, deeply situated foreign bodies are difficult to find and remove. In superficial abscesses, such as those in Cases 5 and 9, the foreign

body was removed, since it was not difficult to locate. In Case 10, we were not able to locate the foreign body at the time of drainage of the abscess, and at that time the Berman locator was not available.

#### SINGLE FOREIGN BODY, WITHOUT INFECTION

The last group consisted of patients who had pain and discomfort referred to the presence of a foreign body, but did not have signs of infection. The following is a typical case.

**CASE 7** I G L., a 28-year-old former medical corpsman, was admitted to the hospital on September 6, 1946, complaining of pain in the right pectoral region of 1 year's duration. On August 12, 1944, he had been wounded to the right pectoral region by an enemy machine-gun bullet. He was hospitalized for 25 days and returned to duty with the wound healed. He was symptom free for 1 year and then began to have pain in the right pectoral region, especially when he used his right arm at work as a machinist.

Physical examination was negative except for a healed wound 3 cm. long and just lateral to the right nipple. There was a diffuse area of thickening beneath the scar measuring 6 by 6 cm. which was tender to palpation.

Anterior and lateral roentgenograms of the chest revealed a ring-shaped foreign body (Fig. 8 and 9) which was removed.

**FIGURE 8** Anteroposterior Roentgenogram of Chest in Case 7 Showing the Shadow of a Metallic Ring Embedded in the Anterior Portion of the Chest Wall

merely knows that a foreign body is present. In Case 7 the location and size of the foreign body undoubtedly accounted for the major part of the symptoms, since the pain occurred in the right pectoral region when the patient raised his right arm or did any strenuous work with the right upper extremity.

#### DISCUSSION

In military surgery, bullets or shell fragments are not usually removed at the time of the initial treatment of the wound or even later unless one or more

**FIGURE 9** Lateral Roentgenogram of the Chest in Case 7 Showing the Shadow of the Metal Ring Embedded in the Right Anterior Portion of the Chest Wall

under ether anesthesia. The object was firmly encapsulated in the pectoralis major muscle and was found to be a ring from an Army pack. Cultures of the area showed no growth. The wound healed by first intention, and the patient was discharged on the 8th postoperative day. He has been asymptomatic since removal of the foreign body.

The treatment of this type of foreign-body reaction may be very simple or may present a most complex problem. It is difficult to determine whether the pain is due to the damage and cicatrix of the original wound alone or to the wound in addition to the retained foreign body, or whether the patient

of the following indications are present that the foreign body is easily found because of its size or location that it is impinging upon a nerve, blood vessel, tendon, joint or bone, that it is a hazard to life or normal function because of its anatomic location, that it is the cause of pain, or that it acts as a focus of infection. The surgery of foreign bodies includes the entire field of general surgery and all the surgical specialties, and with rare exceptions, it is axiomatic that a foreign body is always more difficult to find and remove than is at first apparent.

In this communication we have emphasized the late reactions that may result from foreign bodies in soft tissues, the majority of which become encapsulated with fibrous tissue and cause no symptoms. A variable number of these patients, however, present the problem of infection and pain many

months after the wound has apparently healed. The management of these cases is not at all simple, since the foreign bodies may be small and so numerous, as in the first group discussed above, that removal is not feasible or even wise. If each fragment were removed the trauma of the operation would be extreme. On the other hand, when there is only a single foreign body its removal can be carried out in spite of technical difficulties, and if there are symptoms attributable to this foreign body, removal is necessary in most cases.

A plan for the management and study of these problems includes the basic principles of foreign-body surgery. In the first place the history and physical examination are carefully evaluated to determine the part the foreign body may play in the clinical picture. It must be remembered that the injury of the tissues may be the cause of the symptoms and that the foreign body itself may be only an innocent bystander. A review of the Army medical record is helpful in this respect. Secondly, roentgenologic studies of the location of the fragment are essential before any attempt of removal is made. Thirdly, a decision must be made whether or not to administer penicillin or sulfadiazine. Our policy has been to give penicillin to patients who present signs of infection as soon as they enter the hospital. In cases in which there is no sign of infection and removal is contemplated, penicillin is started on the day prior to operation and continued until the wound is healed. We have given booster doses of tetanus toxoid in all cases. Fourthly when removal of the foreign body is performed, the entire fibrous capsule is removed with the foreign body. Histologic study of the excised material to determine the presence or absence of other foreign matter, such as cloth, should be carried out, in an attempt to prove or disprove the presence of nonopaque material as a factor in the presenting symptoms. Finally, anaerobic and aerobic cultures of the foreign body are made in the operating room. Careful bacteriologic studies in these cases may do much to clarify the late septic reactions. In patients who have multiple small fragments with cellulitis, such as those in the first group discussed above, special attention should be paid to the search for lesions elsewhere, — for example, foot infections, — which may be the portal of entry for intermittent explosive infections.

The basic principles of foreign-body surgery are accurate localization and the control of infection. No attempt at surgical removal should be made until these two factors are properly considered. The use of antibiotics, sulfonamides, tetanus immunization and antitetanic serum have made the surgical technic in these potentially infected, if not actually septic, wounds much safer.

The most accurate localization of the foreign body prior to surgical procedures is paramount. Every surgeon knows that a search for a seemingly easily

accessible foreign body may end in failure. The necessity of accurate localization has led to many an ingenious method of using the roentgenogram and fluoroscope. Films made in two planes with skin markers and two-needle localization under fluoroscopic control are common methods of localization. Reid and Black<sup>6</sup> have described methods of roentgenologic localization. Removal of radio-opaque foreign objects under direct fluoroscopic control is excellent in such regions as the hand and foot, but prolonged exposure of the patient and the operator to the roentgen rays must be carefully guarded against. The Berman "locator" introduced by Moorhead<sup>7</sup> is a surgical divining rod for accurate localization of metallic foreign bodies. It is simple to use, is a sensitive instrument and should be part of the standard armamentarium for surgical removal of metallic foreign bodies. From our experience we are convinced that the "locator" is an important contribution to this particular field of surgery. With the aid of the "locator," the search for the foreign body is greatly shortened in time, and much trauma is avoided. In Case 2 the piece of shell fragment had migrated to the right psoas muscle and was adjacent to the right iliac vessels and the right ureter (Fig 1, 2, 3, 4 and 5). The "locator" pointed exactly to the metallic object, the search for which would have been prolonged, dangerous and even unsuccessful in spite of its fairly large size. An attempt to remove the same foreign body had ended in failure several months before.

### SUMMARY

The problem of late reactions to metallic foreign bodies is presented because of the increase in its incidence after World War II and because of the improvement in its management.

It is probable that there will be an increasing number of such cases in the next few years. Observations on the operative treatment on 11 patients out of a total of 40 are presented, showing that the reactions may be classified into three groups: multiple regional foreign bodies, with cellulitis, single or multiple foreign bodies, with abscess formation, and single foreign body, with local pain. A plan of management is outlined in which the importance of accurate localization and control of infection is stressed.

## CAPILLARY FRAGILITY AND DIABETIC RETINITIS\*

With a Note on the Use of Rutin

RAFAEL RODRIGUEZ, M D,† AND HOWARD F ROOT, M D ‡

BOSTON

**A**N INCREASED incidence of retinal changes among patients with diabetes has been noted in recent years. Diabetes of long duration has been associated with the greatest increase in retinal hemorrhages, although hypertension or other evidences of generalized vascular or renal disease may be present or develop subsequently. The importance of this subject is well known to students of diabetes and to internists, who see increasing numbers of diabetic patients, old and young, with impaired vision from this cause.

The term "capillary vessels" includes the endothelial tubing that lies between the arterioles and the small veins. There is no marked distinction between the smallest capillary arteries, the capillary itself and the venules — Lewis calls them collectively "minute vessels."

The explanation of the cause and nature of increased capillary fragility is obscure. A careful discussion of the skin manifestations is given by Peck and Copley.<sup>1</sup> This phenomenon may occur under a variety of circumstances. Poisons, metabolic substances and vitamin deficiencies directly affect the endothelium. Physiologic variations affect the tonus of the capillaries or indirectly damage the endothelium. Capillary permeability is said to be increased in tuberculosis and in some diseases of the skin. In 1944 the capillary fragility in 18 per cent of 265 selected cases of hypertension was found by Griffith and Lindauer<sup>2</sup> to be increased. Persons with abnormal indexes were believed to be predisposed to retinal and cerebral hemorrhages. Patients with high blood pressure, when treated with thiocyanate, developed a further increase in fragility. Beaser<sup>3,4</sup> studied the capillary fragility in diabetic subjects, the test showed a greater incidence of increased capillary fragility in patients in the fifth and sixth decades and in those with hypertension. Paterson<sup>5-7</sup> discussed capillary rupture with intimal hemorrhages in the causation of cerebral vascular lesions and studied also the vascularization and hemorrhages of the intima of arteriosclerotic coronary arteries.<sup>8</sup> Low capillary resistance was found in 30 of 120 diabetic patients in the University Hospital at Ann Arbor, Michigan, and diabetic retinitis proved to be the most frequently associated abnormality in such cases.<sup>9</sup>

In vitamin C deficiency it is supposed that the loss of the intercellular cement permits extravasation. A relation between low ascorbic acid content in the blood plasma and strength of the cutaneous capillaries in healthy children was seen by Ahlborg and Braute.<sup>10</sup> Greene<sup>11</sup> evaluated the capillary-resistance test in the diagnosis of subclinical scurvy and concluded that a positive reaction does not necessarily denote an insufficient vitamin C intake. At the New England Deaconess Hospital Sebesta, Smith, Fernald and Marble<sup>12</sup> determined the vitamin C blood level of 77 adults with diabetes and found both normal blood values above 0.8 mg per 100 cc and an excretion of the urine of more than 400 mg of ascorbic acid in response to a 1000-mg dose given intravenously. To test the possible relation between vitamin C in the blood and capillary fragility in these patients, a series of simultaneous determinations were made, and it was evident that no relation appeared between the vitamin C content of the blood and the capillary fragility.

Scarborough and Stewart<sup>13</sup> claim that the administration of hesperidin can reduce the number of hemorrhages in patients with vitamin P deficiency. The existence of vitamin P was postulated in 1936 by Szent-Györgyi,<sup>14</sup> who claimed that extracts of Hungarian red pepper and lemon juice contained a substance called citrin or vitamin P.

Studying the deficiency of vitamin C and vitamin P in man, Scarborough and Stewart state that administration of vitamin P does not control the large subcutaneous hemorrhages characteristic of the scorbutic state, these hemorrhages were arrested within twenty-four hours by large doses of ascorbic acid. Vitamin P can produce an increased capillary resistance in the scorbutic subject either before or after treatment with vitamin C. The authors believe that a deficiency of this vitamin may exist in man even after large doses of vitamin C.<sup>15</sup> At the moment it must be admitted that evidence for the clinical value of vitamin P in the absence of a deficiency of this vitamin is scanty.

Rutin, another flavone glucoside, is believed to influence capillary fragility. Rutin is a rhamnogalactoside of quercetin, a derivative of flavanol. It is a tasteless, yellow, nontoxic powder, consisting of masses of microscopic needle-like crystals.<sup>16</sup> Both rutin and hesperidin are constituents of plants — garden rue, tobacco and so forth — and are similar in structure. The chemistry of both is

\*From the George F. Baker Clinic, New England Deaconess Hospital.  
†Formerly, Eli Lilly Fellow, George F. Baker Clinic, New England Deaconess Hospital.  
‡Associate in medicine, Harvard Medical School; physician-in-chief, New England Deaconess Hospital.

described by Couch, Naghski and Krewson,<sup>17</sup> of the Eastern Regional Research Laboratory in Philadelphia. Rutin was first isolated from tobacco. The glucoside was prepared from the flure-cured type of high quality. It was expensive, but the cost is now within the reach of most patients. In an attempt to find a still more economical source of the drug, a number of plants were examined for rutin content, and buckwheat was discovered to be the most promising source.<sup>17</sup>

Several reports have indicated that rutin restores abnormal capillary fragility. Griffith, Couch and Lindauer<sup>18</sup> gave rutin in cases of hypertension, without toxic effects that could be attributed to rutin, nor was there any significant change in blood pressure, and capillary fragility became normal in 8 patients within two months of the beginning of medication. The authors also studied the relation between rutin and crude hesperidin in hypertensive subjects with increased capillary fragility.<sup>18</sup>

Shanno<sup>19</sup> considered rutin more efficacious than hesperidin. He recommended its use in cases of hypertension to maintain normal capillary fragility to prevent vascular accidents. A remarkable change in the character of the bleeding of patients with hereditary hemorrhagic telangiectasia was observed by Kushlan<sup>20</sup> after rutin therapy. These reports indicated that rutin is the most active of chemically related compounds that over the past years have been extracted from various plants. One should consider the use of rutin in any condition associated with an increase of capillary fragility.<sup>21, 22</sup>

Since this botanical drug became available for the treatment of abnormal capillary fragility, we have used it in several cases in which there was evidence of diabetic retinitis and high degrees of capillary fragility. Our studies show that capillary resistance is definitely low in practically all persons with diabetic retinitis. We suggest the desirability of further trial of this substance. More important, however, is the possibility that, through further investigation of the pharmacology of rutin, we may ascertain the indications of its early use, in the hope of preventing the capillary damage related to the retinal and perhaps other degenerative complications in subjects with diabetes of long duration.

#### METHODS OF DETERMINATION OF CAPILLARY FRAGILITY

The correct determination of capillary fragility is essential in the selection of patients for rutin therapy. Peck and Copley<sup>1</sup> discussed a considerable variety of methods by which capillary fragility may be tested, including the suction or negative-pressure method, the positive pressure based on the Rumpel-Leede phenomenon, the direct microscopical observation of the vessel at the end of the nail bed, the puncture and bleeding tests, and the skin tests that employ snake venom.

In measuring capillary resistance, we must consider possibly conflicting results due to differences in technics used by various workers. Cutter and Marquardt<sup>23</sup> studied capillary fragility on the end of the nail bed. Moloney,<sup>24</sup> studying capillary fragility in the newborn, used the negative-pressure resistometer. Beaser<sup>3</sup> concluded that negative-pressure methods are unreliable and that positive-pressure tests, such as Göthlin's method, are commendable. Greene<sup>11</sup> chose the Göthlin method when studying subclinical scurvy. Griffith et al.,<sup>2</sup> of the Eastern Regional Research Laboratory, employed the Göthlin technic in their interesting investigation of hypertension. This procedure requires only a blood-pressure cuff, a magnifying glass and a good light. In the present report we followed the Göthlin positive-pressure test, the technic of which is as follows:

A circular area, 6 cm in diameter, is marked in each antecubital space.

A standard blood-pressure cuff is placed on the arm and a pressure equivalent to 35 mm of mercury is maintained for fifteen minutes. The pressure is lowered, and all the petechiae within the circular area are counted, a good magnifying lens being used.

The process is repeated on the other arm, a cuff pressure equivalent to 50 mm of mercury being employed for the same period. The pressure is lowered, and the findings are noted.

To determine the petechial index, the number of petechiae in the first stage is multiplied by 2, and the number accumulated in the second stage is added. The normal index is 8 (or less), an increased value is 13 (or more), and a borderline (probably increased), 9 to 12.

The present communication is concerned with results of the test for determining the capillary fragility in diabetic patients at the New England Deaconess Hospital. The findings reported deal with three groups of patients: nonselected diabetic patients, diabetic subjects selected with varying degrees of retinopathy, and patients with diabetic retinitis or retinitis proliferans and high degrees of capillary fragility who were treated with rutin.

#### MATERIAL AND METHOD

One hundred unselected young and old diabetic patients, male and female, with short and long durations of the disease, with and without complications, who were routinely studied in the hospital wards and in a diabetic nursing home, had a measurement of capillary fragility by the petechial index of Göthlin, described above.

In 56 selected patients with diabetic retinopathy, the capillary fragility was studied by the same petechial index, with certain minor modifications.\*

\*To save time in these 56 patients the blood pressure cuff was placed on both arms at the same time.

Rutin\* was administered to 70 patients with retinitis and increased capillary fragility, only 20 of whom were adequately followed. The initial dose of rutin was 20 mg three times a day, in the 20 patients adequately followed, the dosage was increased to 40 or 60 mg three times a day.

In all the 156 patients the history was taken and physical examination performed by various members of the medical staff. The presence of retinitis was ascertained by careful ophthalmoscopic examination. In the patients under rutin therapy, the examination was followed by the ophthalmologist, and special attention was paid to the retinal damage and the visual field.

#### RESULTS IN 100 UNSELECTED DIABETIC PATIENTS

The capillary fragility was found to be increased in 44 patients (40 per cent), borderline in 4 (4 per cent) and normal in the remaining 56 (56 per cent).

#### Increased Petechial Index

Diabetic retinitis and hypertension were the most closely related abnormalities among the 40 patients with increased capillary fragility (Table 1).

TABLE 1 Abnormalities in Diabetic Patients with Increased Capillary Fragility

ABNORMALITY	NO. OF PATIENTS	PERCENTAGE
Retinitis with normal blood pressure	14	35
Retinitis with hypertension	12	30
Hypertension only	11	27
Normal fundi with normal blood pressure	3	7.5

The relation of increased capillary fragility to retinitis and hypertension is remarkable. In consideration of this fact, we must mention again the similar results reported by Griffith and Lindauer,<sup>2</sup> Beaser,<sup>3</sup> Rudy and Beaser<sup>4</sup> and Wilder.<sup>5</sup> The following is a review of this group of 40 diabetic subjects in whom the capillary fragility was found to be abnormal.

**Retinitis with normal and high blood pressure**  
Twelve patients (30 per cent) with increased petechial counts had retinitis with hypertension and 14 (35 per cent) had retinitis with normal blood pressure. Table 2 lists the 26 diabetic patients with retinitis with and without hypertension. Among these patients, 13 were women, and 13 men. Six male patients had retinitis proliferans, and in only 2 female patients was this severe degree of retinopathy observed. In the whole group of 8 cases with retinitis proliferans the blood pressure was normal in 2 and above 150 systolic, 90 diastolic, in the remaining 6. Five were men under the age of forty with long duration of diabetes. In all 26 patients, 15 were over and 11 under forty years of

age. The duration of diabetes was eighteen and a third years in the younger and only thirteen and a fifth years in the older group.

**Retinitis with hypertension only** Table 3 presents 11 cases in which hypertension was present with an

cidence of poor capillary resistance with hypertension was 27.5 per cent. The patients were in most cases women in the fifth, sixth or seventh decade of life and with long duration of diabetes. It should be noted regarding the patients in this group that further examination of the fundi must be done over an extended period to observe any changes, especially in cases like the first patient listed in Table 3, a woman aged twenty-nine with diabetes of long duration who showed normal fundi but had hypertension, edema, moderate albuminuria and capillary fragility of 82 petechiae.

\*Obtained from the Eastern Regional Research Laboratory, Philadelphia.

†By hypertension is meant a blood pressure reading of over 150 systolic and 90 diastolic.

*Increased capillary fragility with normal fundi and normal blood pressure* In 3 cases (75 per cent) abnormal capillary fragility was found in patients with normal blood pressure and normal fundi (Table 4). The first 2 patients were ambulatory women with uncomplicated diabetes admitted for routine check-up. The third, a sixty-seven-year-old woman with diabetes of forty years' duration, was admitted as an emergency in mild acidosis and hematemesis of unknown origin (x-ray studies of the gastrointestinal tract and gastroscopy were negative, and coagulation and prothrombin time were normal, but the gastric acidity, as is often observed in

diabetic patients, was below the normal limits), she had also an ulcer in a neurotrophic right foot and the Göthlin count showed 48 petechiae. Later, other youthful diabetic patients showed increased capillary fragility when no evidence of arteriosclerosis could be demonstrated by x-ray examination of the aortic, pelvic or leg arteries. This group of young adults (twenty-five to thirty years of age) confirm the judgment that increased capillary fragility may be present in young persons with diabetes of long duration as one of the earliest signs

of arteriosclerosis, which will subsequently be manifest in nephritis, hypertension and so forth, and general arteriosclerosis.

#### *Borderline Petechial Index*

Griffith and Lindauer<sup>2</sup> found the petechial index to be borderline in 3 cases among a group of 265 cases of hypertension studied. They judge from the occurrence of complications that the borderline group should be called abnormal. In this series of unselected diabetic persons, the capillary fragility was classified as borderline in only 4 cases. Table 5 lists these 4 cases. Two had normal fundi with blood pressures above normal, the duration of

diabetes was five years in one and twenty-five years in the other. A woman aged sixty-nine with diabetes of seventeen years' duration and with hypertension and retinitis is in this group of borderline cases. The use of rutin is suggested in diabetic patients whose petechial counts appear to be borderline.

#### *Normal Petechial Index*

Among the 56 diabetic patients of this nonselected group who had normal counts, in 54 the fundi were normal and only in 2 cases was retinal damage present. A twenty-two-year-old girl with diabetes of fourteen years' duration (Case 28922) and with retinitis proliferans, hypertension, nephritis, gangrene in the right foot, anasarca and uremia had a petechial index of 7. A seventy-three-year-old woman with retinitis proliferans and normal blood pressure (Case 46334) had only 3 petechiae. In a summary of this group of 100 diabetic patients measured by the Göthlin technic, it was found that the index of capillary fragility was above normal in practically all patients who had diabetic retinitis. It seems clear from our observation that diabetic retinopathy seldom occurs in patients who do not have some degree of increased fragility of the capillary walls.

#### RESULTS IN 56 ADDITIONAL DIABETIC PATIENTS WITH RETINOPATHY

That there is a loss of the resistance of the capillary wall in diabetic persons is definite, and it is more evident when one studies selected diabetic patients with early or advanced retinopathy. The distinction between the two is of degree and stage of development. The proliferative type of retinitis often follows a period in which the typical central punctate hemorrhages of diabetic retinitis have been present for months or years. This picture constitutes the most serious menace, aside from arteriosclerosis, nephritis and hypertension, that persons with diabetes of long duration have faced.

In the hope of obtaining the new light on this subject that is so greatly needed, we studied an additional group of 56 selected patients with diabetic retinopathy. They were admitted to the hospital for routine check-up, regulation of diet and insulin or treatment of complications. The petechial index was increased in 47 (83.9 per cent) and borderline in 9 (16.1 per cent) and in no case was found to be normal. To this group of selected cases we add the 26 cases from the nonselected group listed in Table 1, making a total of 82 diabetic patients with retinopathy. The weakening of the capillary wall among these patients is definite, as shown by borderline petechial index in 9 cases and increased petechial index in 73.

#### *Sex*

Studying the effect of diabetes in the development of degenerative vascular diseases, Dry and Hines,<sup>6</sup> found enormously increased vulnerability among

women Schneider et al.<sup>27</sup> who studied the plasma proteins in diabetic retinitis, state that retinitis is more frequent in women. In their 31 cases, 26 patients (84 per cent) were women. Griffith and Lindauer, at the Scientific Exhibit of the American Medical Association in San Francisco in 1946, showed that there was no significant relation between capillary fragility and sex in their hypertensive patients. In our 82 diabetic patients with retinitis and increased capillary fragility, no significant predominancy was found among 44 women as compared with 38 men.

### *Blood Pressure*

In these 82 diabetic patients with retinitis, 39 had normal blood pressures and 43 had pressures above 150 systolic, 90 diastolic.

### *Age of Patient and Duration of Diabetes*

The age is an important factor in the consideration of capillary fragility. Moloney<sup>44</sup> found more or less abnormal capillary fragility in 33 of 55 normal infants but this decreased resistance disappeared as the infant became older. Cutter,<sup>22</sup> in normal adults, showed that the fragility of the capillaries increased in direct proportion to age, and Paterson<sup>4-7</sup> states that the influence of age on the elasticity of capillaries may be an important factor in the causation of intimal hemorrhages. We must say, however, that the duration of diabetes appears to be more important. Rudy, Beaser and Seligman<sup>4</sup> reported that the incidence of increased fragility of the capillaries is great in the fifth and sixth decades and that in diabetic patients a greater incidence is observed at each age decade. It is interesting to observe that of the 82 diabetic subjects considered above 34 (41.4 per cent) were under forty years of age and that some were as young as twenty-one years, the duration of the diabetes, however, was generally more than ten years.

Of the entire group of 82 patients 48 were over forty years, with an average duration of eleven and a third years, and in the 34 patients younger than forty years of age, the average duration of diabetes was seventeen and three fourths years.

An abnormal condition of the capillaries may be an important factor in the production of certain vascular complications that occur in persons with diabetes of long duration. We consider it necessary to measure the capillary resistance in persons who have had diabetes for a long time. The importance of its early recognition is evident. This capillary condition will be the advent of the inevitable "period of exhaustion"<sup>28</sup> of the aging diabetic patient, who now lives longer not only with diabetes but also with degenerative diseases.

### RESULTS OF RUTIN THERAPY

Rutin was administered to 70 patients, but only 20 have been followed adequately. The initial dose

was 20 mg three times a day, and in the 20 patients followed, the dosage was increased to 120 or 180 mg daily after one or two months. No selection was made in this group of patients, whose ages were between twenty-three and sixty-one years, with a duration of diabetes from three to forty years. Twelve had blood pressures above 150 systolic, 90 diastolic. Eight had advanced retinitis proliferans, 6 had severe, and 6 had moderate diabetic retinopathy. To determine the effects of the therapy, capillary fragility was measured every month, and special attention was paid to the retinal picture, visual fields, blood pressure and evidences of sensitivity or toxicity from rutin.

### *Capillary Fragility*

The petechial index became normal or borderline in 5 cases (25 per cent), remained positive but improved in 5 (25 per cent) and was not improved in 10 (50 per cent).

The following cases illustrate the effect of rutin therapy in diabetic patients with retinitis.

CASE 24586. A 23 year-old woman with diabetes of 13 years' duration was examined in 1944 by Dr. W. P. Beetham who found extensive retinitis proliferans with marked new capillary formation and sclerosis of the retinal veins, large hemorrhages and a few areas of cotton and waxy exudate. The visual fields were 20/200 on the right and 20/50 on the left. In April 1946, the visual fields were 6/20 on the right and 6/15 on the left, and extensive retinitis proliferans involved a great portion of each fundus. The blood pressure was 118/86, and the capillary fragility index showed at least 300 petechiae. The patient started taking rutin in April and the capillary fragility was regularly determined each month until April 1947. The first reduction occurred 5 months after the beginning of medication, when the index fell to 182 petechiae. The reading was 56 in January 1947 and was within the normal limits in April. Since July 1946 she was definitely under the impression that her vision had improved but as a matter of fact exactly the same visual acuity was obtained and no modification was seen in the retina. The blood pressure continued unaffected and she had no rash or toxic reactions.

CASE 21518. A 43 year-old man with diabetes of 4 years' duration developed typical central punctate hemorrhages with waxy exudate in each fundus. The visual acuity was 6/7 in each eye the blood pressure was 165/90 and the capillary fragility index was 42 in June 1946. The patient received 60 mg of rutin, and the dosage was increased to 120 mg after 3 months. The capillary resistance became normal after 8 months. The retinal damage and visual field remained the same the blood pressure was also unaffected.

In these cases the capillary fragility became normal with rutin treatment. In the first case, a young diabetic patient with long duration of the disease and with general vascular sclerosis, severe retinitis proliferans and a tremendous increase in fragility of the capillaries, after one year under rutin therapy the petechial index became normal. In the second patient, a man with diabetes of four years' duration, early diabetic retinitis and relatively moderate increase in capillary fragility, the petechial index was reduced progressively and reached the normal counting after eight months.

In the results reported by Griffith and Lindauer<sup>28</sup> in hypertensive subjects, the Göthlin test

normal after four months of therapy, whereas in our diabetic patients with retinitis, only 25 per cent showed normal capillary resistance after eight months or more of therapy

### Retinitis

In no case was an improvement of the visual field or in the retinal picture seen, despite the fact that several patients were strongly convinced that rutin had improved their vision. The retinal picture was unchanged in 13 cases. Two patients had subsequent hemorrhages, and 2 had arterial thrombosis while taking rutin, whereas the hemorrhage was absorbed in 3.

In the patients who had new hemorrhages, the Gothlin test remained increased, and in some cases a rise in the index was seen with the new hemorrhages. A good example is provided by the following case:

**CASE 17242** A 56-year-old man with diabetes of 23 years' duration had hypertension and bilateral diabetic retinopathy, typical punctate hemorrhages were present with vitreous opacities in each eye. The visual acuity was 20/70 on the right and 20/200 on the left, and the capillary fragility index in June, 1946, showed 95 petechiae. For 5 months he was taking rutin daily with progressive reduction of the petechial index, and after 8 months of medication new small hemorrhages developed in the left eye, with a new rise in the capillary fragility. The rutin dosage was increased to 120 and 180 mg, followed by marked reduction in capillary fragility, the petechial index actually dropping to normal. This patient was also under the impression that his vision had improved. However, the visual acuity remained exactly the same.

Another example is provided by Case 27954, in a forty-five-year-old man with diabetes of fifteen years' duration and with diabetic retinopathy and extensive vitreous hemorrhages without ocular hypertonus, who had visual acuity of 20/20 in the right eye and in the left merely perceived a flash-light. The capillary fragility was 24 in October, 1946, and remained abnormally high, with the appearance of subsequent new hemorrhages.

### Miscellaneous

Following these 20 diabetic patients under rutin over a period varying from three months to a year, we have observed that the blood pressure in the entire group was unaffected, and no evidences of toxicity or sensitivity to rutin were seen.

Capillary resistance is definitely low in practically all persons with diabetic retinitis. This abnormality tends to decrease while rutin is being taken and the course of the retinitis is not altered as it was hoped. We should say, however, that rutin was given in the main to patients who already had advanced disease. Thus, the importance of the early recognition of this inevitable advent of capillary damage among patients with diabetes of long duration is evident.

We suggest the possibility that this lack of resistance of capillary wall related to retinitis and hypertension is also related to the degenerative complica-

tions — arteriosclerosis and the nephrotic syndrome — that constitute a specter in the prolonged life of the young diabetic patient.

### SUMMARY

The literature on capillary fragility in relation to diabetic retinitis is reviewed.

Measurements of capillary fragility by the petechial index of Göthlin were done in a total of 156 diabetic patients. Forty per cent of 100 unselected diabetic patients showed an increased capillary fragility. This abnormality was found in practically all patients with diabetic retinitis, whether or not hypertension was present. In 11 cases hypertension was present with increased capillary fragility, but no retinal damage was observed.

In 56 selected cases with retinitis no patients showed a normal petechial index. The petechial index was increased in 47 (83.9 per cent) and borderline in 9 (16.1 per cent).

The incidence of increased capillary fragility was related to the duration of the diabetes more clearly than to the age of the patient, 41.4 per cent of 82 patients with retinitis were under forty years of age, and increased capillary fragility was observed as early as the age of twenty-one years, but with long duration of diabetes.

Rutin was administered to 70 patients with retinitis and increased capillary fragility. The initial dose was 20 mg three times a day, and this was increased to 40 or 60 mg three times a day in 20 cases. (A dosage of 300 to 400 mg daily may be used.)

Increased capillary fragility can be brought to normal with the use of rutin in sufficient dosage, although no patient with retinitis was improved. Increased capillary fragility occurs in diabetic patients as an early evidence of generalized arterial disease and is closely correlated with the development of retinitis and later nephritis.

## FATAL INTESTINAL OBSTRUCTION FOLLOWING INJECTION TREATMENT OF AN INGUINAL HERNIA

KNOWLES B. LAWRENCE, M.D.\*

BROOKLINE, MASSACHUSETTS

THE injection treatment of hernia is now so little practiced in regular surgical circles in New England that its results, favorable or unfavorable, are rarely observed. This report deals with a patient in whom a complete obstruction of the small intestine was attributable to the inflammatory reaction and adhesions produced by the injection treatment of an inguinal hernia.

### CASE REPORT

H. J., a 57-year-old man, was admitted to the Burbank Hospital, Fitchburg, Massachusetts on June 5, 1946, complaining of abdominal distention and constipation of 2 days duration. This patient had had a reducible right inguinal hernia for several years and was currently receiving a series of injection treatments in a nearby town. He wore a truss in the usual way during the course of treatment. The last injection had been given on the morning of June 3. In the afternoon the patient began to feel ill but had no pain. The abdomen gradually became distended; he lost his appetite, passed no gas and became constipated. That night his wife gave him a dose of castor oil, with no fecal results, and the distention increased. He had no nausea or vomiting but when first seen by his physician 2 days after the onset was complaining of moderately intense cramplike pains in the epigastrium.

Physical examination showed the patient to be dehydrated and somewhat toxic. The cardiovascular system seemed normal, and the lungs were clear. The abdomen was greatly distended and tympanitic throughout. No masses could be felt, and there was no localized tenderness. The right inguinal hernia was of medium size and entirely reducible.

The temperature was 98°F, and the pulse 88. The blood pressure was 150/100.

The urine was concentrated with a specific gravity of 1.026 and gave a + test for albumin but was otherwise normal. Examination of the blood disclosed a red-cell count of 4,910,000, with a hemoglobin of 98 per cent (Sahli) and a white-cell count of 5000 with 65 per cent neutrophils and 35 per cent lymphocytes. The blood osmotic pressure was 32 mg per 100 cc. An x-ray film of the abdomen showed several greatly dilated loops with the typical step-ladder pattern of obstruction of the small intestine.

Attempts were made to pass a Miller-Abbott tube but after 24 hours the tube had not passed through the pylorus even

under fluoroscopic manipulation. During the first 2 days in the hospital the temperature remained nearly normal, the pulse ranged between 80 and 90 and repeated white-cell counts were not greatly elevated. The distention continued, however, and emesis in the hospital produced only a very small amount of fecal and gas return. At the end of 2 days he began to have fecal vomiting and fecal drainage from the Miller-Abbott tube which was then lying in the stomach.

Two days after admission when the patient was first seen by the author the findings were essentially as noted above. The patient was only slightly dehydrated, he appeared somewhat toxic. The abdomen was diffusely and markedly distended and tympanitic. Individual loops of bowel could not be outlined perhaps because of the rather obese abdominal wall. The only area of audible peristalsis was adjacent to the right flank. There was no abdominal spasm and no very definite tenderness. The right inguinal hernia was entirely reducible and also omentum. The hernia protruded again spontaneously when the finger was withdrawn from the external ring with the patient recumbent and with just cough or straining. A provisional diagnosis of obstruction of the small intestine possibly due to the adhesions caused by the injection treatments of the hernia was made.

An exploratory laparotomy was performed through a right paramedian incision. Clear straw-colored fluid poured from the peritoneal cavity and loops of greatly dilated and congested small bowel measuring as much as 8 1/2 cm. in diameter in some places presented in the wound. This dilatation of the intestine extended proximally to the ligament of Treitz and distally to a point in the lower ileum about 30 cm. above the ileocecal valve. At this point the small bowel was adherent to the parietal peritoneum of the right internal inguinal ring margin by several broad adhesions which also tended to force a knuckle of bowel distal to this point into the inguinal canal. These adhesions were fresh and freed without difficulty. Some fibrous exudate was also observed on the bowel in this area. These findings suggested that the whole process was of not more than a few weeks' duration. The bowel appeared perfectly viable. The abdomen was then closed without further procedure and without drainage. No attempt was made to repair the hernia itself, since it was believed that it would be unwise to prolong the operation further. The patient was in good condition at that time however with a systolic blood pressure of 120 and a pulse of 80. There was some excess of tracheobronchial secretions, but this cleared in the Trendelenburg position and the breathings then seemed satisfactory. The patient returned to the ward in good condition but expired suddenly and with almost no warning while still under anesthesia almost 2 hours later. Permission for autopsy could not be obtained.

\*Instructor in surgery, Boston University School of Medicine; assistant visiting surgeon, Massachusetts Memorial Hospital.

## DISCUSSION

As pointed out by Maier<sup>1</sup> in a recent report the treatment of hernia by the injection of sclerosing or irritating solutions evoked a great deal of enthusiasm in this country between ten and fifteen years ago. Its protagonists claimed excellent results with a minimum of complications resulting from the treatment itself. Watson,<sup>2</sup> for example, in the second edition of his textbook on hernia published in 1938, stated that he had performed over five thousand injections on 300 patients with hernia, with 95 per cent cures for small indirect inguinal hernias and between 80 and 90 per cent cures for larger or complicated hernias, similar remarkably good results were noted in several series totaling thousands of cases collected by him from the literature. One is impressed, however, by a lack of follow-up statistics based on acceptable time intervals such as one, two and three years in these reports. Watson claimed no serious complications from injection treatment in his own hands and no case of intestinal obstruction at the time of his report.

In 1937 Burdick and Coley<sup>3</sup> reported from the Hospital for Ruptured and Crippled in New York City their findings in a carefully controlled series of 92 cases of hernias treated by injections in an effort to evaluate accurately the place of this treatment. Although a high percentage enjoyed temporary relief of the hernias, these patients continued to wear trusses, and not 1 case was actually cured at the end of a year. Maier<sup>1</sup> reports from the same hospital on a series of 18 operations performed after previous injection treatments. He found marked scarring and atrophy of muscles and obliteration

of normal tissue planes as a result of the sclerosing injections, which made the dissection and satisfactory repair very difficult. In 1 of these cases, obstruction of the small intestine due to incarceration of the bowel in the inguinal canal was encountered. Maier mentions several other cases of strangulated hernia caused by the unyielding "cartilaginous" internal rings produced by the injections. Rice,<sup>4</sup> an enthusiast ten years ago, now finds only a "narrow field of usefulness (for injection treatment) in slender individuals." It also seems significant that no articles favoring injection treatment have been published from responsible surgical clinics in over five years.

## SUMMARY

A case in which recent intraperitoneal adhesions resulting from the injection treatment of an inguinal hernia caused complete simple obstruction of the small intestine is presented in detail. This appears to be a rare complication of the injection treatment of hernia but should be added to a significant list of complications and sequelae that have been reported in the past.

Fortunately, interest in the injection treatment seems to be waning with the realization that this method cannot be depended on for cure of hernia in general.

## THE INCIDENCE OF MULTIPLE LESIONS IN PRIMARY SYPHILIS

IRAN W. KUHLE, M.D.,\* AND HUNTER BOGGS, M.D.†

CHARLESTON, WEST VIRGINIA

ONE of the most popular misconceptions of the medical profession is that the primary lesion of syphilis is always single. In fact, many physicians have been known to eliminate syphilis as a part of the differential diagnosis because the genital lesions were multiple, not single. In our medical-school experience and that of our immediate acquaintances of the medical profession the impression was given that multiple primary lesions in syphilis are rare (in the dozen or so medical schools attended). Medical students and general practitioners can hardly be blamed, since authoritative authors such as Stokes et al.,<sup>1</sup> Sutton and Sutton<sup>2</sup> and Kampmeier<sup>3</sup> declare that multiple chancres are infrequently seen. Andrews<sup>4</sup> and Ormsby and Montgomery<sup>5</sup> mention that chancres are usually single but are frequently multiple.

The limited experience of general practitioners makes them utterly dependent upon these usual sources of knowledge concerning syphilis. Three out of five standard reference books give the impression that multiple chancres border on rarity.

One of us (I.W.K.), while reviewing his medical-school syphilology notes, experienced this impression. As a result, it was decided to determine what the actual figures were at the Kanawha Valley Medical Center, since it was the opinion that multiple primary lesions were not infrequent.

At this clinic we find that multiple lesions are not rare—in fact they are almost as common as single lesions, being approximately 40 per cent of the entire group of cases diagnosed as primary syphilis in 1946. In the literature only two other series of cases were found: Klauder's<sup>6</sup> in 1918 (24 per cent multiple lesions in 200 cases) and Driver's<sup>7</sup> in 1922 (38 per cent in 203 cases). The latter series agrees very closely with our own experience.

In an effort to determine whether these multiple lesions were definitely due to secondary syphilis, we listed separately all untreated, seronegative, dark-field positive cases. This was done in accordance with the general assumption that more than 98 per cent of all cases of secondary syphilis have positive serologic tests. Thus, we have an unselected series of cases that were clinically primary syphilis and a selected series of cases that were still in the seronegative phase. To our amazement an even greater percentage of patients in the latter group had multiple lesions.

In the selection of these cases, penicillin in a small number of doses was not considered as treatment,

whereas arsenicals or bismuth, or both, was considered treatment. The Kahn quantitative serologic test for syphilis, as done by the West Virginia State Hygienic Laboratory, was selected as the index of seronegativity or seropositivity, thereby using a common standard and eliminating various sensitivities—Kanawha Valley Medical Center Laboratory employs the Kahn standard test and Mazzini procedure, in the West Virginia State Laboratory, Hinton, Kolmer and Kahn quantitative tests are done routinely on all admissions.

There was no known bias of the examiners toward single or multiple lesions. At the time the compilation of figures was begun (March, 1947) four of the seven examiners had left this facility, and no such compilation had been anticipated before their departures. Most of the diagnoses were made by five of the seven examiners, and over half by two of them. The period covered was January 1 to December 31, 1946, inclusive.

At Kanawha Valley Medical Center 2023 patients with primary and secondary syphilis, 742 with early latent syphilis and 718 in other stages were admitted. In the unselected cases of primary syphilis the chancres were single in 378 (58 per cent), multiple in 251 (38.5 per cent) and indeterminate<sup>8</sup> in 23 (3.5 per cent). In the selected seronegative cases of primary syphilis the lesions were single in 107 (56.3 per cent), multiple in 82 (43.2 per cent) and indeterminate in 1 (0.5 per cent).

In the untreated seronegative primary cases, there were reinfections in 3, a monorecurrence relapse in 1 and an extragenital lesion (breast of female patient) in 1. In the entire series of primary cases there were reinfections (Stokes criteria were not used by the examiners) in 24, monorecurrence relapses in 16 and extragenital lesions in 10. Of the extragenital lesions observed in this series, only in 1 case were they multiple—so-called "kissing lesions" of the lips. Many extragenital primary lesions were observed, but the majority of patients were admitted in the secondary stage, presumably because of the unfamiliarity of the general practitioners with extragenital lesions and no suspicion of syphilis until a generalized rash appeared.

The oldest patient with primary syphilis was a 75-year-old man, and the youngest a boy of nine. Table 1 compares the sex incidence in selected and unselected cases. As noted many times before, the diagnosis of primary syphilis is made more frequently in male than in female patients. At this center 51.8 per cent of all persons seen (slightly more

\*Claidian, Kanawha Valley Medical Center; senior assistant surgeon (retired) United States Public Health Service.

†Consultant in dermatology and syphilology, Kanawha Valley Medical Center.

<sup>8</sup>"Indeterminate" signifies that the examiner was unable to determine the number of lesions (usually because of phimosis) or neglected to note the number.

than half) were male patients, but in the unselected series of primary cases 87.3 per cent were male and 12.7 per cent were female patients — almost seven times as many males as females — and in

TABLE 1 *Sex Incidence in Selected and Unselected Cases of Primary Syphilis*

SOURCE OF DATA	MALE PATIENTS		FEMALE PATIENTS	
	NO	PER-CENTAGE	NO	PER-CENTAGE
All patients	51	87.3	48	12.7
Unselected series	87	3	12	7
Selected cases	93	2	6	8

the selected series the male preponderance was even greater 93.2 per cent males to 6.8 per cent females, or almost fourteen times as many (Tables 2 and 3)

TABLE 2 *Sex Incidence in Cases Diagnosed as Primary Syphilis*

SOURCE OF DATA	MALE PATIENTS		FEMALE PATIENTS	
	NO	PER-CENTAGE	NO	PER-CENTAGE
Entire series	569	87.3	83	12.7
Patients with multiple lesions	219	87.3	32	12.7
Patients with single lesions	327	86.5	51	13.5
Patients with indeterminate lesions	23	100.0	0	0.0

Thus, in our series it seems not only that more males seek treatment in the primary stage but also that in the earliest stage of diagnosis of syphilis (the

TABLE 3 *Sex Incidence in Selected Cases Diagnosed as Primary Syphilis*

SOURCE OF DATA	MALE PATIENTS		FEMALE PATIENTS	
	NO	PER-CENTAGE	NO	PER-CENTAGE
Entire series	177	93.2	13	6.8
Patients with multiple lesions	77	93.9	5	6.1
Patients with single lesions	99	92.5	8	7.5
Patients with indeterminate lesions	1	100.0	0	0.0

seronegative, dark-field-positive, primary stage) the preponderance in the male is even greater

It is interesting that despite the wide variance of numbers of males and females, the percentage of

multiple lesions is consistent in both series. In the unselected series 12.7 per cent were females, and 12.7 per cent of those with multiple lesions and 13.5 per cent of those with single lesions were females. In the selected series 6.8 per cent were females, and 6.1 per cent of those with multiple lesions and 7.5 per cent with single lesions were females. Thus, the percentages were of the same orders in both series, and there seems to be no tendency for females or males to have single or multiple lesions more frequently than those of the other sex.

## CONCLUSIONS

Multiple lesions are common in primary syphilis — 38.5 per cent of 652 primary diagnoses being multiple.

In 190 seronegative dark-field-positive untreated cases of primary syphilis 43.2 per cent of patients had multiple lesions.

Persons with multiple primary lesions tend to come for treatment earlier than those with single lesions.

Patients with extragenital primary lesions are seldom treated in the seronegative state.

Primary syphilis is no respecter of age.

The diagnosis in the primary stage of syphilis is made much more frequently in male than in female patients — 87.3 per cent and 12.7 per cent respectively.

Male patients seek treatment earlier than females in primary syphilis (93.2 per cent of the former and 6.8 per cent of the latter in the selected "early" series).

There is no recognized tendency for one sex to have multiple primary lesions more frequently than the other.

Extragenital primary lesions are more frequently single than genital primary lesions.

## MEDICAL PROGRESS

## DIABETES

ELLIOTT P JOSLIN, MD\*

WITH THE CO-OPERATION OF LEO P KRALL, MD,† C C BAILEY, M.D.,‡ HOWARD F ROOT, M.D.,§  
PRISCILLA WHITE, MD,¶ AND ALEXANDER MARBLE, MD||

BOSTON

THE following subjects are considered in this progress report on diabetes statistics, diabetic acidosis and coma, the hyperglycemic action of highly purified alkaline phosphatase convulsive states in diabetes, electrocardiographic changes, arteriosclerosis, pregnancy in diabetes metabolism of carbohydrate and fat, the diabetes section of the United States Public Health Service, new rapid blood sugar tests and alloxan diabetes

## STATISTICS

Variations in diabetes mortality in different countries and even in the different states of the United States are so glaring as to arrest attention and demand explanation. Such a diversity of statistical data can be explained partly by different methods of recording deaths, accessibility to medical supervision and availability for statistical enumeration. In this neighborhood the fallacy of estimating the true mortality and much more the computation of the true incidence of diabetes from reports of fatal cases has again been shown by a comparison of the death certificates to a series of deaths of 1000 known diabetic patients only 63.2 were reported as diabetic according to the joint causes of death.<sup>1</sup> The remainder escaped enumeration because of the absence of the word "diabetes" on the certificate, its mention as a secondary cause of death or another disease given priority. Therefore, the Oxford, Massachusetts, survey in which urine and blood specimens of the inhabitants were examined, conducted by Wilkerson and Krall,<sup>2</sup> of the United States Public Health Service, is a major contribution to knowledge of the incidence of diabetes.

The town of Oxford, Massachusetts, has 4983 inhabitants and is diabetes conscious because a children's diabetes camp has been in operation there for seventeen years and these hundred children are an every-day sight on the streets, in bathing or at church. The inhabitants of the town, therefore, were co-operative in the survey, and 3516, or 70.6 per cent, submitted to tests of the blood and urine

For the 40 known diabetic patients in the community prior to the survey 30 persons with unrecognized diabetes were discovered, and if all residents had been examined, the implication is that for each known there was an unknown case of diabetes. Oxford is a representative community, the age composition of the population closely paralleling that of the country as a whole. The incidence of diabetes in the Oxford Survey based on the total population was 0.8 per cent for known cases and 0.6 per cent for newly discovered cases, or a total incidence of 1.4 per cent for the 4983 inhabitants. The ages of the newly discovered diabetic persons

TABLE 1 Prevalence of Diabetes in Oxford, Massachusetts

AGE INTERVAL	TOTAL NO OF PERSONS TESTED	TOTAL NO OF DIABETIC PERSONS
Under 15	931	0
15 to 24	521	2
25 to 34	606	2
35 to 44	444	9
45 to 54	411	19
55 to 64	295	15
65 to 74	192	14
75 and over	69	9
UNKNOWN	2	—

varied between sixteen and ninety-three years, with a median age of fifty-five years, those from forty-five to sixty-four years of age constituting nearly half the cases and more than half the new cases. In the cases in the age decades tested, from forty-five years on, the percentages of diabetic patients found were surprisingly high (Table 1). Thus, between forty-five and fifty-four it was 4.6 per cent, between fifty-five and sixty-four it was 5.1 per cent, and between sixty-five and seventy-four it was 7.3 per cent, rising above the age of seventy-five to 13.0 per cent. If these figures were substantiated by similar figures in larger groups, diabetes would be even a greater geriatric problem than already anticipated.

The sex distribution among the 70 cases revealed 31 men and 39 women. There was a high prevalence of the disease among the French or those of French-Canadian descent. A family history of diabetes was reported by 38.6 per cent of the diabetic and by 18.2 of the nondiabetic persons. Overweight was the rule. The survey showed the unreliability of the fasting blood sugar level as a means of diagnosing early

\*Adjusted on basis of age distribution of the total population of the United States enumerated in 1940

†Less than 10 deaths

Persons with a blood sugar below the screening level and no glycosuria were notified that the tests revealed no laboratory evidence of diabetes. If glycosuria with or without a blood sugar above the screening level was encountered, a further test of urine and blood was given. Dextrose tolerance tests were performed if previous tests of blood and urine

were examined to permit direct comparison, which demonstrated a difference of 20 mg between average venous and capillary blood sugar level.

The ratio of cases of diabetes to the portion of population tested revealed that there were 40 diabetic persons in Oxford under treatment and 30 more cases of the disease discovered, which represents an

incidence of 0.8 per cent known and 0.6 per cent newly discovered cases, or a total incidence of 1.4 per cent for the 4983 inhabitants. Since 29.4 per cent of the townspeople were not reached by the testing program, it is estimated that the number of previously undiscovered cases of diabetes might have risen to 47 had all the townspeople been tested. The 40 known cases in addition to these 47 estimated cases would be equivalent to 1.7 per cent of the population of the town.

The early discovery of diabetes may be considered a form of preventive medicine, because it is generally agreed that the case detected early does the best. Statistics of diabetes discovered by life-insurance examination and of the disease in the medical profession and in the Army, as well as the opinions of doctors intimately concerned with treatment, attest this idea.

This survey is of great importance. It has set a new standard for estimates of the prevalence of diabetes. If the data obtained are duplicated and hold for the country as a whole, the implication would be that instead of 1,000,000 diabetic persons in the United States there are actually 2,000,000. The million *unknown* cases would on the whole be the ones most amenable to treatment, because the majority would be the mild, symptomless cases and those of recent onset, by all standards presenting the best prognosis, but at the same time probably of a lower income group, thus necessitating special provisions for treatment. Moreover they constitute the group *par excellence* for possible obtaining of life insurance and thus may arouse the interest of life-insurance companies — greatly to the advantage of the diabetes situation. On the other hand, one must remember that a small percentage of unrecognized diabetic cases are severe, because the knowledge of the diabetes is first disclosed after entrance to the hospital in diabetic coma. Thus, of 10 patients representing nine decades of life, shown by Joslin in Indianapolis in late 1946, none knew they had the disease until advised of the fact on their recovery from acidosis in the Indianapolis City Hospital. The patients were in the low-income group.

This survey has substantiated the notable and unexpected incidence of diabetes as found among Selective Service registrants by Blotner<sup>2</sup> and by Gates<sup>4</sup> in an industrial establishment.

In a comprehensive discussion of recent studies on diabetes and diabetic patients, Herbert H. Marks,<sup>5</sup> of the Statistical Department of the Metropolitan Life Insurance Company, arrives at the conclusion that the number of *known* cases in the United States is in the neighborhood of 700,000. In any comparison of Mr. Marks's estimate with other estimates, one should bear in mind that figures larger than this include some unknown as well as known cases. He believes that there are 55,000 new cases annually, thus raising his estimate by 5000 since 1946.<sup>6</sup> Approximately 4,125,000, or 2.9 per

cent of the population (2.1 per cent of the males and 3.8 per cent of the females), he considers, will become diabetic before they die. The highest rates are in the urbanized industrial states in the northeast section of the country and the lowest in the southern states and the southwest. Where the Negro population is urbanized and has access to abundant medical and health service, their diabetic death rates are high. For the country as a whole, white and Negro age-adjusted death rates were more than 50 per cent higher in cities than in rural areas, this was true — and even by more than 100 per cent — for the nonwhite population. In the article by Mr. Marks is a table for each state in the

†1935

country, showing crude and age-adjusted diabetes death rates per 100,000 whites and nonwhites separately for 1940 (Table 2).

To Mr. Marks we are also indebted for Table 3, which gives the death rates per 100,000 for diabetes mellitus in various countries of the world for the year 1938. The high rates for the United States and Denmark are significant. It is difficult to understand why England and Wales, Norway, Sweden, Finland and the Netherlands have such low mortalities — 14.0 per 100,000, provisional for 1939 — compared with the neighboring countries of Denmark and Belgium.

The experience of the Metropolitan Life Insurance Company since 1911 shows a steady increase in the crude death rates from diabetes to a maximum in 1940. Since then, the rate has fallen rather rapidly, with the 1945 rate the lowest since 1938. A notable feature of the trend in mortality is the decline recorded during the recent war years. The experience of England shows that "at the low point in 1945, the English death rate from diabetes was more than 25 per cent under the peak of 1940, and more than 20 per cent under the average for 1935-1938."

It would appear that a significant part of the reduction in diabetes mortality recorded in the two wars is genuine and that restrictions on food supply are a factor in this trend. The enforced reduction in food intake tends to ameliorate the condition of many diabetics and also helps to prevent or postpone the onset of the disease in susceptible individuals. In this country, at least, the favorable trend in diabetes during World War II reflects also the absence of serious respiratory epidemics during the entire war period, as well as the success of chemotherapy. This has proved a boon to diabetics not only in combating pneumonia and other infections, but also in the successful management of surgical complications of diabetes. On the other hand, the decline in the diabetes death rate is spurious to some extent in that, with the wartime disruption of medical practices, the reporting of causes of death probably suffered in quality.

The most notable feature of the wartime mortality experience for diabetes is the considerable decline in the death rates in late middle life and old age. The rates in 1944 and 1945 were the lowest in years. However, the recent improvement at the older ages was sufficient to wipe out only a fraction of the long-term increase in the death rates from the disease. Consequently, at ages 65 to 74, the rate in 1941-1945 among males was 34 per cent higher than in the preinsulin years, 1920-1922, and among females it was 81 per cent higher than in 1920-1922.

Statistics on the incidence of diabetes in Mannheim in 1944 were recorded by Oberdisse and Nagel<sup>7</sup> as 190 per 1000 population as compared with 213 for Bavaria and 229 for the whole of Germany. Lombard<sup>1</sup> computed a mortality rate of 5 per 1000 as representing the situation in 1947 in Massachusetts.

A series of patients admitted to the Central Hospital, Borås, Sweden, between 1932 and 1941 have been analyzed and reported by Dahlberg and Grill.<sup>8</sup> At the conclusion of the period a follow-up study showed that 515 patients (66 per cent) were alive, 240 (30.8 per cent) dead and 24 (3.2 per cent) untraced, making a total of 779 cases. Female patients predominated—55.8 per cent of the living and 60.7 per cent of the dead.

An attempt was made to compare the first five years, in which the calculated low-carbohydrate Petrén diet was employed, with the second five years, in which the normal diet was given, but the writers properly point out that the small number of cases and various extraneous factors enter into such a comparison. In the second five years the daily diet varied in carbohydrate between 296 and 369 gm, in protein between 91 and 151 gm, in fat between 94 and 120 gm, and in calories between 2605 and 3127 for individual days. It is evident that the percentage of patients admitted on account of diabetes was less in the second than in the first period, and, correspondingly, the percentage admitted on account of other diseases was greater in the second than in the first period. The fact that insulin was given to 52.5 per cent of patients admitted in the first five years, compared with 74.2 per cent in the second five years, must be considered in any evaluation of the two types of treatment. The cost of insulin purchased by the Central Hospital of Borås for patients treated in the Hospital was 2839 kroner for the first five

years and 6421 kroner for the second five years. Hypoglycemia was present in 5 cases in the first period and in 28 in the second, also showing the greater use of insulin. The average stay was twenty-four days in the first group and twelve days in the second. Coma and pre-coma occurred nearly half less often in the second than in the first period, but here again the influence of insulin and not the diet alone must be taken into account.

Of the 240 deaths, cardiovascular disease accounted for 50 per cent, general and local infections for 16 per cent, and diabetic coma for 5 per cent. Of the 12 deaths from coma, 11 were in females, and the authors state "that these figures indicate a sex difference in resistance to ketone formation." On the other hand, one might compare the 28 deaths from diabetic coma in the Joslin group treated at the New England Deaconess Hospital during a similar period, of whom 8 were males and 20 were females, and the mortality 6 per cent among the males and 9 per cent among the females. The Borås cases, like the Joslin series, show an increasing mortality from coma when it occurs in older people. Their total mortality from diabetic coma in their follow-up was 5 per cent as compared with 3.1 per cent in a follow-up of 651 deaths in the Joslin group for January 1, 1944 to May 15, 1946. The diagnosis "diabetes," which was reported especially in older people, was 10 per cent, and that of tumors was 7 per cent, with 16 deaths from miscellaneous causes. The authors conclude that the probable mortality among diabetic persons is three times as great as that of the general population.

The year 1948 completes my fifty years of practice of medicine and active interest in diabetes. The results of treatment of the cases coming under my supervision and that of my associates under the auspices of the George F. Baker Clinic in Boston were recently published in the Statistical Bulletin of the Metropolitan Life Insurance Company.<sup>9</sup> All my cases, anonymously by number, have been summarized on cards, and the statistical studies have been carried out in the Statistical Bureau of the Metropolitan Life Insurance Company. For the preparation of these statistics 99 per cent of the patients treated since 1898 have been traced, largely as a result of the courtesy of the medical profession in responding to requests for information. The death rates (Table 4) and the increasing longevity of diabetic patients (Fig. 1) give ground for encouragement.

Both the table of mortality and the chart of life expectancy agree in showing that in each successive period of treatment for all ages there has been absolute uniformity in that the results have been steadily improving for each succeeding epoch. The following quotation is illustrative:

At the younger ages these reductions were nothing less than spectacular. Thus at age 10, the death rate in 1922-1925 was 84 per cent less than in the period 1914-1922.

Further sharp gains have been made at every age down to the present, and as before these have been relatively greatest at the younger ages. Thus, even between 1929-1938 and 1939-1945 the most recent of the periods into which the data are divided for comparison, the death rate at age 10 showed a decline of 43 per cent, and at most ages under 45 the reduction between these two recent periods exceeded 30 per cent.

When the rates in the most recent years, 1939 to 1945 are compared with those prevailing before insulin, the revolution in the outlook for diabetics is even more sharply

life at the selected ages of 10, 30, and 50 years in successive periods before and since the discovery of insulin. Prior to 1914 the average 10-year-old diabetic child lived a little more than a year, and during 1914-1922 the expectation of life at age 10 was only a little higher — about 2½ years. The first years of insulin, 1922-1925, saw a gain of nearly 12 years, and marked increases have been recorded in every successive period. Even the most recent period, 1939-1945, shows a gain of a little more than 5 years in the expectation of life at this age over 1929-1938. Today with an expectation of life of 45 years, the average diabetic

§Insulin era.

defined. At age 10, the recent rate is 99 per cent less than in 1914-1922. Reductions of 95 per cent or more are found at all ages up to 30 and of 90 per cent to 95 per cent at ages 30 to 40. Even at age 60, the highest age shown in

child of 10 in this experience may expect to reach his 55th birthday.

Analysis of the causes of death among diabetics in this experience shows further what insulin and other advances

### Experience of George F. Baker Clinic, Boston Massachusetts 1897 to 1945

FIGURE 1 Increasing Longevity of Diabetic Patients (Reproduced from Statistical Bulletin Metropolitan Life Insurance Company\* by Permission of the Publishers)

the table the rate in 1939-1945 was 53 per cent less than in 1914-1922.

Figures for expectation of life of diabetics computed from the mortality rates observed among these patients of the George F. Baker Clinic likewise attest the very great improvement in the outlook for persons with the disease. The chart on page 7 shows the expectation of

in the treatment of diabetes have accomplished. Before insulin diabetic coma snuffed out the lives of practically every diabetic child and of many diabetic adults. The death rate in recent years from this cause is 99 per cent less than in pre-insulin days. The mortality from gangrene, which was a frequent cause of death of diabetics in earlier years, has been reduced nearly 60 per cent. The mortality

from infections, to which diabetics are particularly susceptible and which in pre-insulin days were highly fatal, has likewise been cut radically the death rate from pneumonia to one sixth of the pre-insulin rate, and from tuberculosis to one eighth.

The chief causes of death which show little or no reduction in mortality are the cardiovascular-renal diseases and cancer, but this is not surprising in view of the similar trends in the general population and in view of the in-

992, or 13 per cent of the total. The authors compared the mortality experience among diabetic patients of the Mayo Clinic with that of white persons of the general population in 1930, the approximate mid-point of this experience.

Table 5 shows the death rates per 1000 by age in this experience by ten-year age groups. The death

creasing average age of the diabetic patients in this experience.

Despite the very satisfactory improvement in the prognosis for diabetics demonstrated by this experience, further substantial gains can be achieved. The length of life of patients in this experience is, at every age, still about one fourth less than that of the general population.

Berkson, Gage, and Wilder<sup>10</sup> have made life tables for diabetic patients based upon the experience of patients observed at the Mayo Clinic between 1923

TABLE 6 *Life Expectancy of Diabetic Patients of the Mayo Clinic Compared with that of the General Population by Sex and Age (1923-1938, with Patients Traced to 1940)*

\*Expectancy for diabetic patients calculated by method of Reed and Merrell for constructing an abridged life table.

and 1938 and traced, for the most part, through 1940. The authors included all patients diagnosed as diabetic except those who at the original observation also had a malignant neoplasm. Their series consists of 7408 patients, most of them residents of the middle West. Unlike most clinical series, male patients outnumbered female. The proportion of children was unusually small. In addition to the main group a separate analysis was made of cases free of "associated diseases", this group numbered

rates are at their lowest level at the childhood and early-adult ages, and rise sharply after the age of forty. The yearly death rate at all ages for the total experience adjusted to the age distribution of white persons in the general population in 1930 was 25.2 per 1000. This is approximately two and a half times the death rate for the white population of the country in 1930. For cases free of "associated diseases," the rate was 19.5, or nearly twice the figure for the general population. The rate for females was about 10 per cent less than that for males, in the general population in 1930 the difference was 16 per cent. The comparison with the general population is more favorable at the older than at the younger ages. At most ages under forty, the death rates among the diabetic persons were more than three times as high as the 1930 figure for the general population, between ages ten and twenty, they were more than seven times as high.

Figures on expectation of life computed from the mortality rates observed are shown in Table 6 and the corresponding figures for white persons in the general population in 1930. At age ten, the expectation of life for diabetic patients in the Mayo Clinic experience was 37.8 years as compared with 56.6 years in the general population. The figures decline steadily with age, as do those in the general population. At most ages, the figures for the diabetic patients were about a third less than those for the general population in 1930.

The results of this analysis conform to those reported for patients of the George F. Baker Clinic, although the figures are not strictly comparable, principally because of the difference in the periods

covered in the two experiences. The analysis of the George F Baker Clinic records shows a steady increase in the longevity of diabetic persons since the discovery of insulin.

### DIABETIC ACIDOSIS AND COMA

The essential feature emphasized at the New England Deaconess Hospital and responsible for the improvement in mortality of its cases of coma during the last seven years is the attitude that every case of diabetic acidosis and coma is a grave emergency and that the patient needs intensive study, to determine the diagnosis and especially to determine the complications present, as well as an immediate effort to determine the amount of insulin needed and to give that dose as promptly as possible. Occasional, profoundly unconscious patients may need 500 to 1000 units, and if any less than this dose is given in the first few hours, delay occurs at a time when it is most dangerous. Those who adopt automatic rules by which a patient gets 50 units every thirty minutes may find in the occasional very severe case that in the first two or three hours only a comparatively small amount of insulin has been given and during that time the patient has lost ground.

The striking improvement in the mortality rate of profoundly unconscious patients at the Deaconess Hospital has been due to willingness to give 500 or 1000 units, or even more, in the first two hours of treatment when it is necessary. Thus, whereas 35 per cent of the profoundly unconscious patients died in the period before 1940, since 1940 only 10 per cent have died. Everyone knows that the mortality in the profoundly unconscious patient is higher than that in patients who are not yet completely unconscious. Thus, Nicholson and Branning<sup>11</sup> report a mortality of 64.6 per cent in 55 patients in coma who were profoundly unconscious. When they omitted from this series unconscious patients whose deaths were due to complications other than coma, they still had a mortality of 48.8 per cent. Another striking fact brought out in their article had to do with the use of sodium lactate. Thus, patients who received sodium lactate showed a mortality of 8.5 per cent for those twelve hours in coma, 66.6 per cent for those in coma from twelve to twenty-four hours and 50 per cent for those in coma for twenty-four hours. Patients treated without sodium lactate showed a mortality of 9.1 per cent for those twelve hours in coma, 22.2 per cent for those in coma twelve to twenty-four hours and 66.6 per cent for

3 patients in coma for twenty-four hours. Little advantage was obtained by the use of sodium lactate. They also described 2 cases of diabetic acidosis associated with a decrease in the serum potassium concentration, with recovery in 1.

Shock may occur with coronary occlusion, as in Case 24095 with a fall in the blood carbon dioxide to 20 vol per cent but with no acetone bodies in the blood. Differential diagnosis is therefore important. This case might have been thought to be a death from diabetic coma if there had not been quantitative measurement of the acetone bodies in the blood, which showed less than 2 mg total acetone bodies per 100 cc.

In the treatment for diabetic acidosis of 96 children, Hartman and Ergasian<sup>12</sup> made use of sodium lactate to raise the blood carbon dioxide. The method is summarized by the statement that insulin is immediately administered in amounts of 2 units per kilogram of body weight, and 30 cc of sixth-molar sodium lactate solution per kilogram of body weight is given intravenously. At the same time 40 cc of hypotonic Ringer's solution per kilogram and 30 cc of sixth-molar sodium lactate per kilogram of body weight are given subcutaneously. Six hours later approximately 0.5 unit of insulin per kilogram is administered, and if necessary sixth-molar sodium lactate is given subcutaneously and plasma, concentrated albumin or whole blood as required. Five of the 96 children died, although acidosis was relieved before exitus.

(To be continued)

### CASE 34121

#### PRESENTATION OF CASE

A sixty-six-year-old housewife entered the hospital with swelling of the right leg

Two weeks prior to admission, following a day of standing at the election polls, swelling of the right leg appeared, with slight aching referred to the hip and lower back. A physician advised bed rest, which resulted in definite improvement during four days' rest, but upon arising the swelling and discomfort returned.

Physical examination revealed a comfortable patient with marked pitting edema of the right leg, extending to the thigh. The extremity was cyanotic and cool, with moderate venous distention and diminished arterial pulsations on that side. A small area of tenderness was found over the calf. Homans's sign was negative. There was also slight edema of the left lower leg. No other abnormal signs were observed.

Examination of the blood disclosed a red-cell count of 4,400,000, with a hemoglobin of 15 gm, and a white-cell count of 5900, with 69 per cent neutrophils, 22 per cent lymphocytes and 9 per cent monocytes. Urinalysis was negative, and the prothrombin time was normal. An x-ray film of the chest was normal.

Following admission heparin and dicumarol therapy were instituted, and the patient was maintained with a prothrombin time of 40 to 60 seconds (control, 18 seconds) for about two weeks, following which she was allowed up with a constricting dressing on the right leg. During this period the temperature occasionally reached 99°F, and she complained of vague pain in the upper lumbar area. An intravenous pyelogram showed the right kidney to be displaced to the right by a mass that extended 5 cm to the right of the lumbar spine. A barium enema revealed an abnormality of contour having the appearance of extrinsic pressure just distal to the hepatic flexure, which was moderately displaced. A gastrointestinal series showed the duodenum to be quite definitely displaced, principally anteriorly, but also slightly to the left. A diver-

ticulum extended from the second portion of the duodenum. No other contributory findings were discovered by x-ray examination.

About four weeks following admission, an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR HORATIO A ROGERS I am sure that I should see the x-ray films before I go any farther.

DR STANLEY M WYMAN The lung fields appear clear. The heart shadow is not remarkable. There are no visible mediastinal or hilar masses. The film of the abdomen shows dye in the right urinary passages and a smooth, somewhat spindle-shaped mass extending to the right of the spine, compressing the upper pole of the kidney on the right and displacing it laterally. This is well seen in the oblique view. There is no unusual area of calcification. There are no other visible masses in the abdomen. The liver and spleen do not appear remarkable. The displacement of the colon is seen here, with the suggestion of an extrinsic pressure defect in the proximal transverse colon. The duodenum is displaced considerably anteriorly in this film, but one cannot outline the mass well.

DR ROGERS The finding of edema of the leg without previous symptoms is in favor of a local rather than a systemic cause of swelling. Direct pressure or venous thrombosis could account for the swelling of one leg and the partial swelling of the other leg only if it involved both right and left branches of the bifurcation of the vena cava, which would make the thrombosis or pressure area quite low down in the vena cava. The swelling is not suggestive of a thrombotic condition arising from the deep veins in the calf because of the absence of Homans's sign, and we do not have to suppose that it was that when we go on and find a mass, which by the organs it displaces must be a retroperitoneal mass in the location where it could partially obstruct the abdominal vena cava and perhaps also cause thrombosis. If all that is true, the question comes down to the nature of this retroperitoneal mass in a sixty-six-year-old woman, which was not immediately fatal and which caused no severe pain and no fever. The absence of fever and the white-cell count enable us to rule out an inflammatory mass fairly well. If it were an abscess in the retroperitoneal region of sufficient size to displace the organs, as it usually does, it would have to be tuberculosis of the spine, and it is unlikely that the spine would not show some evidence of erosion. So I think we can dismiss that possibility.

If it were a retroperitoneal hemorrhage, we would expect a somewhat lower hemoglobin level and red-cell count and severer pain at the time the hemorrhage occurred. Also, it would have to be a very extensive hemorrhage to form a retroperitoneal hematoma large enough to displace the organs as described. If it were a cyst of that size, it would

almost have to be one of either the kidney or the ovary, and we would expect mention of its being felt on abdominal examination.

That brings us down to neoplasm in the retroperitoneal space as the most likely possibility. Can we go farther and try to guess the nature of the retroperitoneal neoplasm? Sixty-six is definitely in the cancer age, which means less and less as people see malignant tumors in all age groups, but the fact remains that there is a higher incidence in elderly people than in young people. Is there any kind of carcinoma that this could have been? It is very unlikely. There is nothing to make one think of the gastrointestinal tract or the ureter, and I think that we will have to say that it was not a primary cancer in the retroperitoneal space. It was presumably not metastatic cancer in the retroperitoneal space because there were no previous symptoms to suggest the existence of a primary carcinoma, and such a huge metastatic mass would be strange without an obvious explanation for its presence. So it must have been some kind of neoplasm of the sarcoma or lymphoma or lymphosarcoma type, if it was a neoplasm. There is a condition (retroperitoneal lipoma) that I have never seen and that is found in middle-aged people, women more than men, and often contains areas of cancer and sometimes areas of hemorrhage. It becomes very large, and it would be capable of producing this picture, I think. It could be a retroperitoneal sarcoma of almost any type, or it could be a retroperitoneal lymphosarcoma. This patient's age is not against that, and we have no way of knowing which it was but so long as I am quite likely to be wrong anyhow, I think I shall guess that it was a rare disease and say that this woman had a retroperitoneal lipoma with thrombosis of the veins producing edema of the right leg.

DR CLAUDE E. WELCH: May I ask Dr. Rogers if he would have operated on the patient?

DR. ROGERS: I am ashamed to say that I did not consider that point in studying the protocol. The patient was apparently getting better, and although no diagnosis was possible without operation, I should think it was very questionable how much operation could accomplish in the way of permanent cure. I probably would have to operate to make the diagnosis but would not be hopeful of curing her. Perhaps a course of x-ray treatment would have helped rule lymphosarcoma in or out without operation.

DR. ROBERT R. LINTON: I should like to say a word about the edema of the right leg. I doubt whether the tumor caused the swelling of the right leg because a tumor mass pressing on the inferior vena cava should cause the left leg to swell also. The unilateral edema suggests to me a deep venous thrombosis of the right leg.

DR. WYMAN: From the x-ray point of view a lipoma might be expected in most cases to show rarefaction. Not necessarily, of course, but that

might be a lead against lipoma. This lesion looked homogeneous in density.

## CLINICAL DIAGNOSIS

Retroperitoneal sarcoma

DR. ROGERS'S DIAGNOSES

Retroperitoneal lipoma

Venous thrombosis

## ANATOMICAL DIAGNOSIS

*Malignant lymphoma, lymphoblastic type*

## PATHOLOGICAL DISCUSSION

DR. WELCH: It is an interesting point that Dr. Linton made. We see 3 or 4 patients each year with thrombophlebitis in the extremities as the first sign of abdominal cancer, and we were interested to discover whether or not there was direct involvement of the vena cava in this case to account for the thrombosis. We operated with a diagnosis of retroperitoneal sarcoma. A long transverse incision was made, and we found, as the x-ray film has shown, the kidney displaced downward and laterally. The large tumor was intimately adherent to the vena cava, which was not thrombosed. We suspected the histologic nature of the tumor as we palpated it and proceeded with the excision of the tumor mass. Other small but definitely enlarged lymph nodes were noted about the celiac axis.

DR. TRACY B. MALLORY: The tumor that we received in the laboratory showed a malignant lymphoma of relatively undifferentiated character, which we diagnosed as lymphoblastic lymphoma. Following operation the patient made a smooth convalescence and is now undergoing x-ray therapy.

DR. LINTON: How large was the mass?

DR. WELCH: I should say 11 by 7 by 6 cm.

DR. ROGERS: Do you think that standing on her feet for such a long period was the cause of the episode of edema?

DR. WELCH: We thought that it was.

DR. ROGERS: Was the mass movable with changes of gravity?

DR. WELCH: No, it was firmly fixed.

## CASE 34122

### PRESENTATION OF CASE

A sixty-nine-year-old watchman entered the Emergency Ward because of difficulty in voiding of two months' duration.

During this period repeated instrumentation and catheterization were required, and blood clots were passed in the urine from time to time. Voiding was difficult, delayed and in small amounts. Episodes of epigastric pain followed by vomiting were reported, but the history was vague and erratic. Bowel habits were normal and without diarrhea or melena.

A 40-pound weight loss in the six months before entry was reported

Physical examination revealed an emaciated, pale, drowsy, chronically ill man, with a hot, dry, wrinkled skin. The heart and lungs were not remarkable except for a few extrasystoles. The abdomen was scaphoid and difficult to palpate, some resistance was encountered in the right upper quadrant, but no tenderness, mass or liver edge could be made out. Rectal examination was negative, the prostate was of normal size, with a slightly granular consistence. The left scrotum was enlarged four or five times normal.

The temperature was 101.2°F, the pulse 80, and the respirations 18. The blood pressure was 105 systolic, 60 diastolic.

Examination of the blood revealed a red-cell count of 3,800,000, with a hemoglobin of 8.5 gm, and a white-cell count of 8200. A stool examination showed a ++++ guaiac reaction, and the vomitus a ++ guaiac reaction. Urinalysis disclosed a +++ test for albumin, with numerous red cells and occasional white cells in the sediment. The non-protein nitrogen of the blood was 45 mg per 100 cc, the total protein 5.6 gm, the fasting blood sugar 96 mg, the calcium 7.6 mg and the phosphorus 2.6 mg per 100 cc. The chloride was 100 milliequiv per liter, and a van den Bergh reaction was normal. The amylase was 38 units per 100 cc, and the alkaline phosphatase 3.8 units. An intravenous pyelogram showed right-sided calyceal blunting without ureteral dilatation, this was later confirmed by a retrograde pyelogram, with the demonstration of a bladder stone. Chest films and a barium enema were not remarkable. A gastrointestinal series demonstrated an obstruction at the antrum, with an area of marked narrowing 3 cm in length, but a normal-appearing duodenal bulb was seen. Cystoscopy revealed moderate trabeculation and a 2 cm oval, granular, whitish stone on the bladder floor, no tumor was seen.

After completion of studies it was agreed that the patient should be prepared for surgical exploration. On the fifth hospital day, however, he developed sudden, severe, nonradiating, right-lower-quadrant and right-upper-abdominal pain, with associated physical findings of lower-abdominal distention, tympany, rumbling peristaltic rushes and marked deep right-lower-quadrant tenderness, there was no spasm or rebound tenderness. Impacted barium was removed from the rectum, with slight relief. An upright abdominal film showed no subdiaphragmatic air and no dilated loops of bowel. A Levine tube was passed, and the patient vomited 1500 cc of brown watery fluid, which was equivocal on guaiac test. The symptoms subsided gradually, and parenteral fluid therapy was again directed toward surgical preparation. Two days later he had a similar sudden, severe episode, with the same findings and

another normal abdominal film. Relief was again obtained by aspiration of gas and 500 cc of fluid from the stomach.

An operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR ROBERT R. LINTON: As one reads the record, this patient obviously had something much more seriously wrong with him than the genitourinary condition when he came to the Emergency Ward. He had difficulty in voiding of two months' duration. I believe, however, that that had very little to do with the condition for which I am supposed to discuss this case. Obviously, he had a bladder stone, and I assume that that and perhaps some obstruction from the prostate were the reasons for the difficulty in voiding. In addition, he had a mass in the left side of the scrotum due to a large scrotal hernia or hydrocele, probably the latter. These, I think, are unrelated, although it is possible that if it were a hernia, one could connect the episode described later on with an incarceration and perhaps partial obstruction of the small intestine. It is interesting that very little vomiting is mentioned during the hospital admission, and yet the vomitus is reported guaiac positive. It is also significant that the stool examination showed a ++++ guaiac reaction. Those findings suggest that he was suffering from some lesion in the gastrointestinal tract that had produced blood in the stools. The x-ray examination, I think, reveals the source of bleeding, both in the stools and in the vomitus. Before going farther we might see the x-ray films.

DR STANLEY M. WYMAN: The chest appears within normal limits for a patient of this age. The lesion described in the gastrointestinal tract is seen in the region of the antrum and prepyloric region on these two films and is well seen on these two spot films. There seems to be a constant narrowing that does not change in contour. There is a suggestion of a normal mucosal pattern, but that is not definite. The point about the films that interests me is this irregularity in the upper second portion of the duodenum, which is not mentioned in the record. It is a constant finding on all the films, and there seems to be a suggestion of shelf formation distally and possibly proximally on the lesser curvature. On the medial aspect of the duodenum there is an accumulation of barium that may be in a diverticulum or an ulcer crater. I do not see the duodenal cap adequately outlined on any film. I cannot comment further on that. This brings up the question whether or not there were one or two lesions in the upper gastrointestinal tract. The colon shows nothing remarkable. A film from the pyelogram shows a stone in the bladder. I think the blunting of the calyces on the right is minimal. The left kidney is displaced downward, but I do not know why.

DR LINTON Do you know anything about the six-hour or twenty-four-hour film? Was there any gastric residue?

DR WYMAN That is not included in the series of films that I have here

DR LINTON It is certain that one has to take the roentgenologist's opinion of this finding as showing evidence of a lesion in the distal end of the stomach and a questionable lesion apparently in the second portion of the duodenum. Would you say that the duodenal loop is widened at all?

DR WYMAN No, there is no widening

DR LINTON I ask that because a wide duodenal loop frequently means a malignant or inflammatory lesion involving the pancreas

We do not know too much about what happened during the stay in the hospital except that operation was decided on. The patient suddenly developed upper abdominal pain, lower abdominal distention and rumbling peristaltic rushes, and when a Levine tube was passed down the stomach he vomited 1500 cc of brownish watery fluid. I assume that he must have aspirated some fluid as well as this large amount that he vomited. One-and-a-half liters is considerable residue in anyone's stomach — especially one who is not taking a great deal of nourishment by mouth. The episode apparently repeated itself, and again 500 cc was aspirated.

It seems to me that the diagnosis in this case is very obvious, and for that reason I am probably wrong. We are dealing with a patient who has a lesion in the pyloric end of the stomach, which constricted the lumen sufficiently to cause dilatation of the stomach with retention of gastric secretions and food taken by mouth. I have ruled out small-bowel obstruction since the small bowel was not dilated. As a matter of fact, when I was a resident here (in the days before the Levine tube was used routinely) I helped one of the visiting men operate on a patient for small-bowel obstruction because of large peristaltic waves seen in the right lower quadrant, and much to our amazement the patient had acute dilatation of the stomach and no small-bowel obstruction whatever. The patient responded very well to simple lavage and drainage of the stomach. It is my opinion that the patient in the case under discussion had a lesion of the distal portion of the stomach involving the pyloric end, which, in view of the positive guaiac test on the stool and vomitus, suggests a malignant lesion. I am unable to rule out or in a lesion involving the second portion of the duodenum, but in view of the fact that we have no evidence in the x-ray report that there is marked constriction in the duodenum, I believe that the lesion is more likely to be in the distal end of the stomach. My diagnosis is carcinoma of the pyloric end of the stomach, with pyloric obstruction.

DR ALFRED KRANES If there were a lesion in the second portion of the duodenum, would you consider anything else?

DR LINTON One would have to consider carcinoma of the head of the pancreas, which is unusual without some evidence of jaundice due to obstruction of the common bile ducts.

DR KRANES I was thinking of lymphoma with multiple lesions, if that observation is correct.

DR LINTON That is a good suggestion. I had not thought of a lymphoma here. Malignant lesions of the distal end of the stomach would probably cover it.

DR WYMAN I am at a disadvantage because the examination is not complete. Benign ulcer of the duodenum could produce this picture in the duodenum, and there might have been an ulcer of the prepyloric region that had resulted in scarring.

DR LINTON The fact that the stool gave a + + + + guaiac reaction is a little against a duodenal ulcer due to cicatricial contraction, because such patients do not bleed much, but again the blood could have arisen from the mucosa of the dilated stomach.

DR WYMAN If the duodenal lesion has a crater, with associated spasm, the bleeding is possibly explained.

DR LINTON Yes

#### CLINICAL DIAGNOSIS

Carcinoma of stomach

#### DR LINTON'S DIAGNOSIS

Carcinoma of pyloric end of stomach

#### ANATOMICAL DIAGNOSES

*Duodenal ulcer, active*

*Chronic gastritis*

#### PATHOLOGICAL DISCUSSION

DR TRACY B. MALLORY This patient was explored, and a very large, old, indurated ulcer was found in the second portion of the duodenum on the posterior wall. A subtotal gastric resection was performed, and no lesion was found in the stomach other than a mild hypertrophic gastritis. Following operation attention was finally drawn to the complaint for which he came in. The bladder stone was duly crushed and removed, and a small amount of prostatic tissue around the mouth of the bladder was removed. After multiple operations the patient went home with a good recovery.

DR KRANES What was the cause of the right-lower-quadrant pain?

DR MALLORY Acute gastric dilatation, so far as we know — nothing else was found.

## DIABETES — A MASS EXPERIMENT IN THE STUDY OF ARTERIOSCLEROSIS

Two papers on diabetes in this issue of the *Journal* bear witness to the continuing importance of the disease despite the advances that have been made in its control. The diabetic group furnishes, in particular, an unusual group for the study of the degenerative diseases, for although its members live on the average for fourteen years after the diagnosis is made, 67 out of 100 succumb to hardening of the arteries. We may expect, therefore, from recent evidence,\* that the degenerative changes of old age should be further deferred and life prolonged beyond the present sixty-four years by an organized and

intelligent study of this group, employing the most modern methods.

The bounds of the experiment are definite. Here is a homogeneous group of 1,000,000 patients with known and 1,000,000 persons with undiagnosed diabetes, two thirds dying of arteriosclerosis with the average duration of their diabetes now fourteen years, and their average age at death sixty-four years. The extension of any one of these frontiers is an achievement dependent upon the individual efforts of both patient and doctor. Like the athlete and his trainer, success will be found where the partnership between the two has been the closest.

The data already obtained in this mass experiment show its importance. How is it that coronary thrombosis is eight times as frequent in diabetic as in nondiabetic women? Why are calcified pelvic arteries found in 46 per cent of 79 young persons who have had diabetes for twenty or more years with only 1 such case noted in 75 nondiabetic persons of similar age? Of what significance is the demonstration that the chance of obtaining a living child from a pregnant diabetic mother is only 20 per cent if the pelvic arteries are calcified but more than 90 per cent if they are not calcified? Why should 20 cases of calcification of the vas deferens be observed in diabetic patients compared with 1 case in a nondiabetic person?

The participation of endocrinologic factors may be studied since diabetes itself is conditioned by a deficiency of a specific hormone, insulin. Biochemical analyses of humoral factors, of which the lipid cholesterol may be mentioned, are rapidly accumulating. The influence of metabolic and infectious agents is under scrutiny.

The discovery of the cause for the premature advent of degenerative changes of old age in a person with diabetes will have far-reaching consequence for the whole human race.

## THE GENERAL PRACTITIONER ORGANIZES

THE general practitioner of medicine, after centuries as the leading exponent of his profession, is at last having efforts made to restore to him some-

\*Diabetes Exhibit, Interim Session, American Medical Association January, 5-8, 1948

thing of this position, even in an age of science that seemed to have passed him by

The American Medical Association established a section on general practice in 1946, and in June, 1947, on the occasion of the centennial convention of the Association in Atlantic City, the American Academy of General Practice was founded. The wheel has completed its cycle. Each of the major divisions of medicine that split off from the main body of this art has achieved its special rating and its special privileges, the parent and protector of them all has at last been stirred to seek its own salvation.

There have been organizations of general practitioners before now — to wit, every state medical society and the American Medical Association itself, a hundred years ago. This is the first time, however, that general practice has raised its voice to be heard throughout the nation, as distinct from the voices of its offspring — perhaps in self-protection against those lesser, if more sparkling, satellites.

The purposes of the Academy as avowed in its constitution are praiseworthy: to promote and maintain high standards of the general practice of medicine and surgery, to encourage and assist young men and women in preparing, qualifying and establishing themselves in general practice, to preserve the right of the general practitioner to engage in medical and surgical procedure for which he is qualified by training and experience, to assist in providing postgraduate study courses for general practitioners, and to encourage and assist practicing physicians in participating in such training.

To be eligible for membership a physician must be engaged in general practice, he must be licensed in the state in which he practices, he must be of the usual high moral and professional character. He must have had at least one year of rotating internship at an approved hospital or the equivalent in postgraduate training, and he must have been in general practice for at least three years.

This new organization of general practitioners is not novel, nor are its purposes in any way original, unless we consider it as being quite different in its aim and ideals from the sometime association of physicians who called themselves Asklepiads. Threatened groups or groups that wish to extend

their influence have always organized, and organization is as old as the family, the tribe or the pack.

The general practitioner, hardy and independent as he is, has had his livelihood threatened by better organized minorities. He has been passed by, over-ridden and denied the privileges of those certified by boards and has found access to hospitals difficult. Organization for self-protection and *self-improvement* has been necessary. In this organization, however, he does not wish to be patronized, and he does not need to be flattered. He knows his worth to the community, and if the community does not know it, it can be taught.

---

## NEGRO HEALTH WEEK

NATIONAL Negro Health Week has been planned for April 4 to 11 by the Office of Negro Health Work of the United States Public Health Service. This particular observance is not the result of any recently exploited circumstances, the movement was originated in 1915 by the Negro race's own great leader, Booker T. Washington, whose birthday on April 5 will fall within the designated period.

After Dr. Washington's death the program that he initiated was annually conducted at Tuskegee Institute, at which time Founder's Day was celebrated and the National Medical Association and the John A. Andrew Clinical Society held their meetings. At this time, also, clinics were held at the Institute's John A. Andrew Memorial Hospital, the gift of members of the family of Massachusetts' great abolitionist and Civil War governor. A number of Northern physicians have been guests at these gatherings and have carried away pleasant recollections of the hospitality and courtesy extended to them.

The current health week, while bringing to light some of the problems that confront the Negro, will also, it may be hoped, discover more and more helping hands extended toward him — a greater spirit of co-operation in furthering his adjustment to an environment not originally of his own choosing.

The President's Committee on Civil Rights has recently issued its report proposing 'the enactment by the States of fair health statutes forbidding discrimination and segregation based on race, creed,

color or national origin, in the operation of public health facilities"

This is all very well, and fair laws make fine reading. What is needed, however, is not so much new laws as a new spirit of tolerance and co-operation and understanding. Through all the history of the world there can be found running an unbroken thread of man's humanity to man. When that thread can be broadened into a convincing pattern then may countless thousands cease to mourn.

## MASSACHUSETTS MEDICAL SOCIETY

### DEATHS

FLEMING — Edwin R. Fleming, M.D., of Medford, died on March 4. He was in his sixty-ninth year.

Dr. Fleming received his degree from Jefferson Medical College of Philadelphia in 1904. He was a member of the New England Obstetrical and Gynecological Society and a fellow of the American Medical Association.

His widow survives.

HEALY — Thomas R. Healy, M.D., of Newburyport, died on February 25. He was in his seventieth year.

Dr. Healy received his degree from Dartmouth Medical School in 1899. During World War I he was chief of the X-Ray Department of the United States Marine Corps and the United States Navy. He was a member of the American Roentgen Ray Society, New England Roentgen Ray Society, Radiological Society of North America and American College of Radiology and was a fellow of the American Medical Association.

A brother, a nephew and a niece survive.

HOWE — Oliver H. Howe, M.D., of Cohasset, died on March 1. He was in his eighty-eighth year.

Dr. Howe received his degree from Harvard Medical School in 1886. He was a former president of Norfolk South District Medical Society.

Four sons survive.

RICE — John Dexter Rice, M.D., of West Boylston, died on October 4. He was in his thirty-third year.

Dr. Rice received his degree from Tufts College Medical School in 1940.

His mother, father, three brothers, a son and two daughters survive.

## A HUNDRED YEARS AGO

The following remarks, by Dr. H. J. Bigelow, of Boston, on a subject first brought to the notice of the profession by himself, in the pages of this *Journal*, are entitled to consideration. He believes that profound narcotism can always be produced by the use of ether or chloroform and that within a short time, no surgeon will commence a formidable or nice operation upon a patient who has not arrived at this stage of *anaesthesia*. When ether is used, inhalation should be of *air impregnated with ether, and passing through it, and not of ether alone*, as from a sheet bag or sac. He has had a good opportunity

of testing the effects of chloroform in his own and other operations, and, indeed, has used no ether since its introduction. It seems to him to be thus far identical with ether in its effects, much stronger and portable, it does not infect the clothes, is less irritating to the lungs, and is at first quite palatable to the patient. In his opinion, it must supersede "ether" of which it is but a variety. — One achievement prepares the way for another and we are again taken by surprise with a new preparation which is to be known under the name of *Collodion* — being a solution of *gun cotton* in ether. Mr. Samuel L. Bigelow, a senior student at the Harvard Medical School informs us that from Dr. Charles T. Jackson he learned the manner of preparing it, for Dr. Jackson had remarked upon it and exhibited specimens before the National History Society, in Dec. 1846 or Jan. 1847, and enumerated various uses to which it might be applied — among others, as a brilliant varnish. For this use Mr. Bigelow soon after prepared a bottle, according to the directions. While engaged in employing it in this way, he accidentally smeared with it a fresh wound on his finger. The smarting called his attention to it, and he endeavored immediately to rub it off. It had dried, however, instantaneously, and remained on. The smarting very soon ceased, and when the film was removed, perfect union had taken place. Since this time, the efficacy of this preparation as a dressing for wounds has been tested, especially those which it is desirable to unite rapidly, by first intention. *Collodion* would seem to possess very eminently, all the requirements for producing such a union. Mr. Bigelow is informed that a series of experiments are being now made at the Mass. General Hospital, by the surgeons in attendance, who will be soon able to test its value and range of application. — Speaking of the Hospital, a copy of the late report of the institution was sent to the editor several days since. From page 10 to 46, the trustees have devoted to the history of the discovery of ether inhalation, and they have taken strong ground, too, in their 4th conclusion, in saying, "The whole agency of Dr. Jackson in this matter appears to consist in his having made certain suggestions, which led Dr. Morton to make the discovery — a discovery which had for some time been the object of his labors and researches." Although drawn up with an air of candor and fairness, this report will be memorable in the series of annual accounts of that beautiful establishment from the circumstance that it bears a history of the ether war. There are no more indications of peace between the rival candidates for favor, than there is between this Government and Mexico. — Another donation of \$100,000 has nearly found its way into the treasury of the institution. At this rate, it will ultimately become immensely rich. Five hundred medical students should be daily learning the details of their profession there. — We take this opportunity to men-

tion, that when a communication is intended for a leading article in this *Journal*, it should be received at the Editor's office not later than Monday of the week preceding that in which the article is to be published. Two pages of each number are left open till Monday morning, which is the latest period for the receipt of brief notices etc. — Extracted from the *Boston Medical and Surgical Journal*, March, 1848

R. F.

## MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

### DEPARTMENTAL PUBLICATIONS

The following is a list of publications sent out regularly by the Massachusetts Department of Public Health. They are available to anyone upon request.

*Blood Donor News* (bimonthly) contains news regarding schedules of the mobile unit, collection and distribution of blood, and progress and changes in the program.

*Cancer Bulletin*, a quarterly bulletin for physicians, contains abstracts of important papers on cancer research, diagnosis and treatment.

*Cancer Tidings*, issued bimonthly, is a news letter sent out to members of the co-operative cancer-control committees giving the latest news on cancer-control programs being carried on in the Commonwealth.

*Communicable Disease Information*, sent out weekly, gives up-to-the-minute news of the reported cases of communicable diseases in Massachusetts.

*Contact*, a quarterly bulletin prepared by the Division of Maternal and Child Health containing articles and recommendations on school health work, is primarily directed to school superintendents and school nurses.

*News Letter*, a monthly bulletin, contains articles and news of general interest to all health workers.

*V D Bulletin*, a quarterly for physicians, is designed to disseminate information regarding current advances in the treatment and control of venereal diseases.

### APPOINTMENT OF DR FIUMARA

Dr Nicholas J. Fiumara has been appointed director of the Division of Venereal Diseases of the Massachusetts Department of Public Health, after certification by the Division of Civil Service of the Commonwealth. Dr Fiumara is a graduate of Boston College and Boston University School of Medicine. Since his return from service with the Navy, Dr Fiumara has received the degree of master of public health from the Harvard School of

Public Health. He is a fellow of the Massachusetts Medical Society and the American Medical Association and a member of the Massachusetts Public Health Association and the American Public Health Association.

## MISCELLANY

### NATIONAL HEALTH ASSEMBLY

A National Health Assembly will be held in Washington from May 1 to 4 according to Oscar R. Ewing, federal security administrator. The Assembly is the result of President Truman's message of January 30 requesting the development of national health goals for the next ten years.

The activities of the Assembly in initiating this ambitious program will be largely in the form of panel discussions, each panel to explore fully a specific phase of the health problem. An anticipated contribution of the Assembly will be a clearer picture of how much agreement there is in certain supposedly controversial health fields.

### BELGIUM HONORS DR. RICHARD P. STRONG

The Belgian ambassador, Baron Robert Silvercrux, in an intimate ceremony at Dr. Richard P. Strong's residence on February 7 presented him with the cross of Officer of the Royal Order of the Lion. This award, which had been granted by an executive order of February 24, 1947, was in recognition of the pioneer work that Dr. Strong had performed in 1926 and the following year, when he led a medico-biologic expedition into Liberia and the Belgian Congo.

The Order of the Lion is one of the highest ranking Belgian decorations. It was conferred on Dr. Strong through the offices of the Secretary for Colonies and indicates the high esteem in which he is held in Belgian scientific and colonial circles.

### MARKLE FOUNDATION AWARDS

Among the sixteen scientists appointed as the first group of scholars in Medical Science under the John and Mary R. Markle Foundation plan are Christian B. Anfinsen, Ph.D. (A.B. Swarthmore College, S.M., University of Pennsylvania, Ph.D. Harvard Medical School) to Harvard Medical School in the field of biochemistry; Edward J. Beattie, Jr., M.D. (A.B., Princeton University, M.D. Harvard Medical School) to George Washington University School of Medicine in the fields of surgery and cardiorespiratory physiology; and Henry D. Hoberman, M.D. (A.B. and Ph.D. Columbia University, M.D., Harvard Medical School) to Yale University School of Medicine in the field of biochemistry, particularly in the study of compounds by the use of isotope tracers.

### APPOINTMENT AT COLUMBIA UNIVERSITY COLLEGE OF PHYSICIANS AND SURGEONS

Dr. Otto Lowenstein was recently appointed clinical professor of neurology at Columbia University College of Physicians and Surgeons.

## CORRESPONDENCE

### BILIRUBIN AND THE RENAL FILTER

To the Editor: I have read with great interest Dr. Lawrence E. Young's review "Current Concepts of Jaundice with Particular Reference to Hepatitis" which appeared in the August 14 and 21 issues of the *Journal*. On a single point, however, a fundamental misunderstanding of the facts is put forward in this valuable study.

Dr. Young is of the opinion that the occurrence of bilirubinuria in the different forms of jaundice is explained by the fact that bilirubin-globin—the "indirect" bilirubin,

hemolytic jaundice and retention jaundice — cannot pass the renal filter, whereas the free sodium bilirubinate ("direct" bilirubin) present in the serum of patients with regurgitation jaundice does. This opinion is quite erroneous, for it has long been known that all bilirubin present in serum is bound to the albumin fraction of the serum protein — be it globin or common serum albumin — and consequently does not filtrate or pass by diffusion the kidney membrane or any other semipermeable membrane. This has been shown by dialysis, electrophoresis and ultrafiltration, as pointed out by Snapper and Bendien in their articles entitled "Abtrennung von Serumkolloiden durch Ultrafiltration" (*Acta breo Neerlandica* 1 69-71, 1931) and "On physico-chemical condition of bilirubin in bloodserum and urine" (*Acta med Scandinav* 98 77-82, 1939), by Bennhold in his paper entitled "Über die Viskositätsfunktion der Serumweißkörper" (*Ergebnisse d inn Med* 42 273-375, 1932) and by Pedersen and Waldenström in a study entitled "Studien über das Bilirubin in Blut und Galle mit Hilfe von Elektrophorese und Ultracentrifugierung" (*Ztschr f physiol Chem* 245 152-162, 1937). The results of these investigations are in perfect agreement with the well known facts that cerebrospinal fluid, sweat, saliva, tears and almost all secretions and excretions, with the exception of urine and bile, are free from bilirubin even in long-standing severe jaundice, as demonstrated in the literature cited in my paper "Bilirubin in urine and other secretions apart from the bile and in the cerebrospinal and eye liquors" (*Acta physiol Scandinav* 10 355-365, 1945). Bilirubin is thus a rather singular substance from the point of view of the kidney physiologist, since it is not excreted by filtration in the glomeruli but solely by secretion in the renal tubuli. The linkage between bilirubin and the serum albumins is very firm and can only be loosened by means of the active cellular work of the liver cells and the cells of the tubuli of the kidneys. This linkage of the serum bilirubin to the serum albumins — including possibly globin from hemoglobin — is also of great interest for the understanding of the pathogenesis of jaundice. For it is very difficult to understand how bilirubin passes through the capillaries into the tissue spaces and colors the various yellow tissues. I have tried to solve this difficult question by means of a provisional hypothesis in my recent paper "Pathogenesis and different forms of jaundice" (*Acta med Scandinav* 128 25-41, 1947).

TORBEN K. WITH, M D

Rigshospitalet  
Copenhagen

Dr With's letter was referred to Dr Lawrence E. Young, whose reply is as follows

*To the Editor* Although it is now recognized that some substances are excreted by the kidney only as a result of work by the tubular cells, the term "renal filter" is still rather liberally applied in references to the kidney in current medical literature. Boyd, for example, in discussing "indirect" bilirubin in his *Textbook of Pathology* (fourth edition, P 542) states "This type of bilirubin cannot pass the kidney filter." On Page 541 of the same text the following statement is found "If the altered bilirubin is then reabsorbed into the blood, as in obstructive jaundice, it is able to pass the barrier of the renal filter and appears in the urine." Numerous references of this sort could be cited, and in addition the term "renal barrier," which has similar connotations, is currently employed by many writers. Hanger, for instance, states in Cecil's *Textbook of Medicine* (seventh edition, P 856) that "the delayed indirect fraction is retained by the renal barrier."

I agree with Dr With that, in the light of present knowledge, more specific terms might well be used in describing various types of renal activity. It should be made clear, however, that in my review on jaundice I was merely following current usage of the term "renal filter" and was not expressing a personal opinion that bilirubin is excreted by glomerular filtration.

Dr With's informative and thought-provoking paper, "Pathogenesis and Different Forms of Jaundice," raises a number of questions that can be answered only by further experimental and clinical observations. In particular, the manner and extent of the binding of bilirubin by protein and the mechanism by which bilirubin leaves the circulation are not yet clear. The active separation and excretion of pro-

tein-bound bilirubin by renal tubular cells, if it occurs, is without precedent according to modern concepts of renal physiology.

Anyone interested in jaundice will profit from consideration of the material presented in Dr With's recent review.

LAWRENCE E. YOUNG, M D

Strong Memorial Hospital  
Rochester, New York

## RESTORATION OF LICENSE

*To the Editor* At a meeting of the Board of Registration in Medicine held February 19, it was voted to restore the registration to practice medicine to Dr Nathan Gaber, 129 Mt Vernon Street, Boston, as of February 21, 1948.

H QUIMBY GALLUPE, M D, Secretary

State House  
Boston

## "NEGATIVE BRONCHOSCOPY"

*To the Editor* As an ardent follower for over ten years of the Case Records of the Massachusetts General Hospital, I cannot help taking this occasion to raise a question concerning certain statements appearing under Case 34022 in the issue of January 8. This was a case of bronchogenic carcinoma occurring in a lower-lobe bronchus. There was peripheral suppuration and contraction of one of the basal segments, a situation commonly referred to loosely as "atelectasis." There was nothing particularly remarkable about the case as a whole. Bronchoscopy had revealed an inflamed, edematous mucosa with marked obstruction and some purulent secretion. The lobectomy specimen revealed carcinoma and rather extensive bronchiectasis. The surprising thing was the comment by Dr Donald King, seconded by Dr Benedict, that he could not recall such a case with "a negative bronchoscopy." I think anyone who has done much chest work will agree that such a situation is not only not rare but also relatively common among a large group of bronchogenic carcinomas, and that many of them cannot be positively diagnosed by the most expert bronchoscopists prior to exploratory thoracotomy. Furthermore, the bronchoscopy was not actually "negative," except in the sense that it did not clearly reveal tumor. It seems probable that the statement conveyed a different impression than was actually intended. In any event it was most certainly inaccurate.

F J LOVELOCK, M D

Chest Service  
Bellevue Hospital, New York City

Dr Lovelock's letter was referred to Dr Donald S. King, whose reply is as follows

*To the Editor* Thank you for referring Dr Lovelock's letter to me. He has just cause for alarm. The statement as published "I cannot remember any case with cancer in a bronchus with a negative bronchoscopy" is of course not true. I cannot be sure what I said. What I meant to say was "I cannot remember any case with cancer in one of the segmental bronchi to the basal segment of a lower lobe in which we were unable to make a correct diagnosis by means of bronchoscopy." I have not been able recently to review our series of some hundreds of cases of primary bronchogenic carcinoma, but so far as my memory goes the statement as corrected above must still stand. These segmental bronchi are usually easily visualized at bronchoscopic examination. I did not make it clear that I was distinguishing between cancer in the basal segment in the lower lobe and that occurring in the dorsal segment of the lower lobe, the middle lobe or the upper lobe. Bronchoscopic visualization is much more difficult in these areas.

DONALD S. KING, M D

1101 Beacon Street  
Brookline, Massachusetts

## HEALTH MENACE IN CROWDED TRANSPORTATION FACILITIES

*To the Editor* It is to be hoped that the members of the Massachusetts Legislature will realize that the problem of meeting the transportation needs of southeastern Massachusetts as a result of the announced discontinuance of train service on the Old Colony Railroad has its medical as well

as its economic aspects. If the Metropolitan Transit Authority takes over this responsibility and continues its policy of furnishing 60 or even as many as 80 seats for every 100 passengers, it will mean crowded cars and many passengers standing. Crowded cars afford an opportunity for the easy and rapid spread of respiratory infections during a period when an epidemic is prevailing. The tired worker or businessman, who must stand all or much of his way home is quite susceptible to infection; his disposition is not improved by a trying trip from work, and he does not contribute to a happy home. It makes one shudder to think that many more thousands may be added to the crush and pushing in already overcrowded trains and subway stations.

Sound public health policy demands a seat for every commuter. It demands protection of the older and handicapped person in the rush for the car door and seats. It is evident that adequate and comfortable transportation facilities will reap a benefit in the health and efficiency of the public that will compensate for possible deficits in operation of transportation facilities.

HAROLD L. HIGGINS, MD

Newton

## BOOK REVIEWS

*Deal by the Tail*. By Langston Moffett. 8° cloth, 431 pp. Philadelphia: J. B. Lippincott Company, 1947. \$3.00.

This novel tells the story of a man afflicted with a perpetual desire for alcohol. He traveled the world over and finally after fifteen years of drunkenness conquered his desire by self-renunciation and with the help of love. This powerful story is well written and the plot well sustained to the end. It should be in all special collections on alcohol.

*Medicine in the Changing Order*. Report of the New York Academy of Medicine Committee on Medicine and the Changing Order. 8°, cloth 240 pp. New York: The Commonwealth Fund, 1947. \$2.00.

The Committee on Medicine and the Changing Order was organized in 1943 with a membership of thirty-three physicians and seventeen representatives of allied professions and lay persons. The physicians were chosen because of their interest in medical education and public health. The lay members were selected from the fields of ministry, law, social welfare, hospitals, insurance, labor and industry. The objectives of the research were defined as follows: "To be informed on the nature, quality, and direction of the economic and social changes that are taking place now and that are clearly forecast for the immediate future, to define in particular how these changes are likely to affect medicine in its various aspects, to determine how the best elements in the science of medicine and in its services to the public may be preserved and embodied in whatever new social order may ultimately develop." After a preliminary study and investigation lasting sixteen months, eleven subcommittees were formed to study, especially medical education and graduate and postgraduate medical education, internship, the hospital administration of public health services, extension of medical services, the cost of diagnostic and consultant services, industrial medicine, rural medicine, nursing and dentistry. The committee also selected the titles and authors of twelve monographs to be published by the Commonwealth Fund. These monographs have been noted or reviewed from time to time in these columns.

This general report summarizes the work of the committee in the various fields mentioned above. The report opens with a chapter on the origins of present problems in American medicine and concludes with one on "the method and goal." The committee does not approve compulsory health insurance at present and disapproves any form of prepaid full coverage insurance to be applied as suitable for all sections of the country.

In an over-all program the following principles are emphasized: In extending medical service and perfecting its organization, quality must be preserved; provision of public health services is a primary essential; improvement in medical service requires effective use of hospitals with adequate facilities; success will require trained professional and nonprofessional

personnel; for optimal results, organization and co-operation of physicians are required in the improvement of medical services; voluntary prepayment plans are needed; the goal should be comprehensive medical service; extensive education for both physicians and the public will be required; progress in the extension of medical service must be varied and adapted to the needs of the community; and finally Government aid will be required. Each of these points is discussed at length. The report and collateral volumes are well published in a uniform series. The New York Academy of Medicine and the Commonwealth Fund are commended for completion of this valuable study and its publication in an inexpensive form: no volume costing more than \$2.50, the average price being \$1.61 a volume and the price of the complete set being \$20.25. The series is highly recommended for all libraries, medical and general.

*Rhinoplasty and Restoration of Facial Contour. With special reference to trauma*. By Jacques W. Mallinac, MD. 8°, cloth, 327 pp. with 214 illustrations. Philadelphia: F. A. Davis Company, 1947. \$7.50.

As the title of this book indicates, the author has made an attempt to cover the entire field of traumatic surgery of the nose, from the repair of simple septal deviations to the complex reconstruction of nasal loss.

The book essentially a monograph describing the author's approach to the various types of nasal deformities of traumatic origin is divided into thirteen chapters covering 312 pages. The general arrangement of the chapters is good. The volume is well illustrated with photographs and explanatory diagrams. The classification of deformities is somewhat confusing. The diagrams and their legends are not always clear but on the whole are good.

The author justly condemns the use of complicated appliances in the correction of nasal deformities and fractures. However, the reviewer finds that the author contradicts this point when he describes a rather complicated and wholly unnecessary method for the immobilization of comminuted nasal fractures on Pages 94 to 97.

Chapters VI and VII are particularly good. In the former the various types of skin grafts, flaps and supporting structures used in rhinoplasty reconstruction and the relative merits of each are described; the discussion of the place for transplantation of cartilage and bone as well as the sequelae when used improperly is well taken. The latter chapter, which describes the severe types of septal malformations and their correction, should prove useful to many rhinologists.

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*Laboratory Manual of Microbiology for Nurses*. By Elizabeth S. Gill, S.B., instructor in nursing, Department of Nursing College of Physicians and Surgeons, Columbia University; and James T. Culbertson, Ph.D., professor of bacteriology and parasitology, University of Arkansas School of Medicine. 4° paper, 116 pp., illustrated. New York: G. P. Putnam's Sons, 1947. \$1.50.

The authors of this manual believe that nurses should be taught the proper methods of handling pathogenic bacteria and the working exercises in the manual are designed to serve as guides in such instruction under proper supervision. Beginning with work on nonpathogenic micro-organisms for the purpose of teaching the student proper techniques and procedures and the use and care of the microscope, the student is carried forward to the study of the important families of bacteria, the spirochetes, yeasts and molds, protozoans, helminths and arthropods. Two appendices list reagents and solutions, and sources of supply for materials. A list of books for reference concludes the volume. The material is well and conveniently arranged and the manual should prove a valuable for its indicated purpose.

memberships are open to any person interested in blood banking

Requests for applications for membership or general information should be addressed to Miss Marjorie Saunders, LL B, Secretary, American Association of Blood Banks, 3301 Junius Street, Dallas, Texas

#### AMERICAN PUBLIC HEALTH ASSOCIATION

The seventy-sixth annual meeting of the American Public Health Association will be held in Boston from November 8 to 12 inclusive. Representatives from all parts of the United States, from Canada, Cuba and Mexico and from Latin American countries, as well as delegates from Europe and Asia, will attend. The following related organizations will hold their annual meetings at the same time and in the same place as the Association: American School Health Association, Association of Maternal and Child Health and Crippled Children's Directors, Association of Reserve Officers of the United States Public Health Service, Association of State and Territorial Health Officers, Conference of Municipal Public Health Engineers, Conference of Professors of Preventive Medicine, Conference of State and Provincial Public Health Laboratory Directors, Conference of State Directors of Health Education, Council of State Directors of Public Health Nursing, National Committee of Health Council Executives, and Public Health Cancer Association.

An extensive scientific program is in preparation, with particular attention to problems of public-health dentists, engineers, epidemiologists, food and nutrition specialists, health officers, industrial hygienists, laboratory workers, maternal and child health experts, public-health educators, public-health nurses, school health specialists and vital statisticians.

#### RESIDENCY IN PSYCHIATRY AT JOSEPH H PRATT DIAGNOSTIC HOSPITAL

A new residency in psychiatry for one-year service is immediately available at the Joseph H Pratt Diagnostic Hospital, Boston.

Service will consist largely of diagnosis and management of patients with neuroses and with personal and emotional complications of disease. Applicants should have an internship as a minimum of training.

In general residencies will begin on January 1 or July 1, except for the residency mentioned above.

Applications should be addressed to Mr Richard T Viguers, administrator.

#### MEDICAL ASSOCIATION OF THE STATE OF ALABAMA

The annual meeting of the Medical Association of the State of Alabama will be held in Mobile from April 15-17 (secretary, D L Cannon, M D, 519 Dexter Avenue, Montgomery 4, Alabama).

#### ARKANSAS MEDICAL SOCIETY

The annual meeting of the Arkansas Medical Society will be held in Little Rock from April 15-17 (secretary, W R Brooksher, M D, 602 Garrison Avenue, Ft Smith, Arkansas).

#### CALIFORNIA MEDICAL ASSOCIATION

The annual meeting of the California Medical Association will be held in San Francisco from April 11-14 (secretary, L H Garland, M D, 450 Sutter Street, San Francisco 8, California).

#### FLORIDA MEDICAL ASSOCIATION

The annual meeting of the Florida Medical Association will be held in St Augustine from April 12-14 (secretary, Robert B McIver, M D, Box 1018, Jacksonville 1, Florida).

#### LOUISIANA STATE MEDICAL SOCIETY

The annual meeting of the Louisiana State Medical Society will be held in Monroe from April 12 to 14 (secretary, P T Talbot, M D, 1430 Tulane Avenue, New Orleans 13, Louisiana).

#### TENNESSEE STATE MEDICAL ASSOCIATION

The annual meeting of the Tennessee State Medical Association will be held in Nashville on April 13 and 14 (secretary, W M Hardy, M D, 706 Church Street, Nashville 3, Tennessee).

#### SOCIETY MEETINGS AND CONFERENCES

## TUFTS COLLEGE MEDICAL SCHOOL

### Postgraduate Division

### Courses for the General Practitioner

**INTERNAL MEDICINE**, commencing April 6 for one or three months  
 Didactic lectures, conferences, and demonstrations of clinical applica-  
 tions. Special emphasis on proved diagnostic and therapeutic  
 methods. Dr. Robert P. McCombs in charge. Tuition fees one month  
 \$100 three months \$250

**CARDIOLOGY**, April 6-8. Practical applications of diagnosis and  
 therapy emphasized. Dr. Hiram Magendanz in charge. Tuition fee \$40

**OPHTHALMOLOGY**, April 6-30. The treatment of the commoner  
 external eye diseases taught through demonstration. Instruction in  
 the proper use of the ophthalmoscope with interpretations of the  
 normal fundus and fundus lesions in relation to general medicine. Dr.  
 Joseph I. Sperber will conduct the course at the Boston City Hospital.  
 Tuition fee \$75. Ophthalmoscope required

**DERMATOLOGY**, April 12-16. Diagnosis and treatment of com-  
 mon skin diseases, occupational dermatoses reviewed according to  
 toxicology, practical management, and medical aspects. Dr. John G.  
 Downing in charge. Tuition fee \$40

**RADIOLOGY**, May 13-14. A three-day full time course in chest-ray  
 Normal anatomy, physiology and pathology will be demonstrated  
 including roentgenologic interpretations of the heart and lungs in health  
 and disease. Dr. Alice Ettinger in charge. Tuition fee \$25

All courses may be taken under the G.I. Bill of Rights  
 upon presentation of a VA Certificate of Eligibility

## GRAFTON CONVALESCENT HOME

### A Best and Convalescent Home for Discriminating People

Located in the hills of New England, Grafton, Massachusetts, 32 miles from Boston, 36 miles from Providence, Rhode Island, and 8 miles from Worcester. Built at a cost of \$200,000. A quiet, homelike atmosphere with elegant furnishings. Excellent care by registered nurses in constant attendance. Best of foods served. Private and semi-private rooms at reasonable rates. Competent physicians on call at all times. Patients may have their own physicians or special nurses, if desired. We can take ambulatory or bed patients, including terminal cancer, all drainage cases, diabetes and other chronic diseases. Inspection and correspondence invited.

Telephone — GRAFTON 2124

MRS. ALICE T. JOHNSON, R.N., Superintendent  
 20 CHESTNUT AVENUE, GRAFTON, MASS.

## IT DOES HAPPEN HERE

*Severe rickets still occurs—even in sunny climates*

Vitamin D has become such an accepted practice in infant feeding that it is easy to think that rickets has been eradicated. However, even deforming rickets is still seen, as witness the above three contemporary cases from three different sections of the United States, two of them having well above the average annual sunshine hours for the country. In no case had any antiricketic been given during the first two years of life. *It is apparent that sunlight did not prevent rickets.* In other cases of rickets, cod liver oil was given inadequately (drop dosage) and even this was continued only during the winter months.

*To combat rickets simply, inexpensively, effectively—*  
**OLEUM PERCOMORPHUM**

This highly potent source of natural vitamins A and D, if administered regularly from the first weeks of life, will not only prevent such visible stigmata of rickets as pictured above, but also many other less apparent skeletal defects that might interfere with good health. What parent would not gladly pay for this protection? And yet the average prophylactic dose of Oleum Percomorphum costs less than one cent a day. Moreover, since the dosage of this product is measured in drops, it is easy to administer Oleum Percomorphum and babies take it willingly. Thus there is assurance that vitamin D will be administered *regularly*.

### OLEUM PERCOMORPHUM WITH OTHER FISH-LIVER OILS AND VIOSTEROL

Potency, 60,000 vitamin A units and 8,500 vitamin D units per gram. Supplied in 10 cc and 50 cc bottles, and as capsules in bottles containing 50 and 250

## THE TREATMENT OF ARTERIAL EMBOLISM\*

RICHARD WARREN, M.D.,† AND ROBERT R. LINTON, M.D.‡

BOSTON

ALTHOUGH doctors since the time of William Harvey may have had some conception of the pathologic physiology of thrombosis and embolism and although John Hunter,<sup>1</sup> in 1794, reported intravascular coagulation occurring during life it was not until the time of Virchow<sup>2</sup> (1845) that arterial embolism was clearly described and until later in the century (1895) that the operation of embolectomy was first attempted by Ssabanejeff<sup>3</sup> in Russia. From then until 1911 embolectomy was performed a dozen or more times without success before Labey<sup>4</sup> first successfully removed an embolus from the femoral artery. A short time later Key,<sup>5</sup> in Sweden, was also successful. During the next ten years, Key demonstrated the possibilities of the operation and expanded its use to the utmost in the medical system of Sweden. In ten years Swedish authors were able to report results in 382 cases of embolectomy for arterial embolism of the extremities.<sup>7</sup> At that time numerous small series were first reported from clinics in this country,<sup>8-14</sup> so that by the year 1932 the medical profession had been able to form some preliminary conclusions regarding the place of surgery in this condition.

These conclusions were that arterial emboli usually occur in patients with heart disease who are in middle age, that the most common site of lodgment is a bifurcation of a major artery, usually the bifurcation of the femoral vessels, and that removal of the embolus before ten hours from onset have elapsed often, but not always, saves the limb. Simultaneously with the acceptance of these general conclusions a step forward was taken in the conservative treatment of acute arterial occlusion. Intermittent positive and negative pressure was introduced by Herrmann and Reid,<sup>15</sup> and intermittent venous occlusion by Collens and Wilensky.<sup>16</sup> The oscillating bed has been a more modern improvement on this principle. The role of arterial and arteriolar spasm in acute occlusion and the possibility of relief by interruption

of the sympathetic pathways, either surgically or otherwise, were becoming familiar in 1934.<sup>17, 18</sup> It was at the same time that the purification of heparin by Charles and Scott<sup>19</sup> to the point where it could be used therapeutically furnished a logical means of preventing the blockage of vital collateral circulation by the distal propagating thrombus that follows embolism.<sup>20, 21</sup> With these new weapons available a few authors have suggested that surgery in the treatment of arterial embolism should be, if not abandoned, at least relegated to a position secondary to the newer conservative methods.<sup>18, 22, 23</sup>

It was with these considerations in mind that we undertook to examine our own experience with arterial emboli to determine what place, if any, the operation of embolectomy should play in the therapy of this condition. We have carefully studied the records of 98 patients who suffered 172 arterial emboli during the period 1937 to 1946.

When we first examined the record we discovered that although the operation is well known and the condition is presumably common, embolectomy was performed only forty-three times in twenty-two years.<sup>24, 25</sup> This is a frequency of two operations per year in a hospital to which an average of 6842 patients are admitted and in which an average of 4637 operations are performed each year. That this infrequency is not confined to our hospital, however, is testified to by the small size of most individual series reported and by the fact that McClure and Harkins<sup>26</sup> found only 690 cases reported in the world literature in thirty-three years.

For a better consideration of the disease as a whole, the first section of this paper is devoted to statistical matters concerning all emboli wherever lodged, the second section being confined to the limb emboli for which more specific means of therapy are available.

### GENERAL CONSIDERATIONS

#### *Sites of Embolism*

Figure 1 shows the sites of lodgment of the 172 emboli in the series. Of the total group 110 cases, or 63.9 per cent, occurred in the limbs. Table 1

\*From the Surgical Service, Massachusetts General Hospital, and the Department of Surgery, Harvard Medical School.

†Associate in surgery, Harvard Medical School, assistant surgeon, Massachusetts General Hospital (chief, Surgical Service, Veterans Administration Hospital, West Roxbury, Massachusetts).

‡Associate in surgery, Harvard Medical School, visiting surgeon, Massachusetts General Hospital.

presents a comparison of the sites of peripheral emboli with other figures from the literature

There is a constant statistical trend of incidence at the various sites regardless of the source of the figures. It must be emphasized that the data presented in Figure 1, which shows the frequency of the diagnosis of emboli to the brain, spleen, kidney and skin, were obtained from clinical statistics as listed in a diagnosis file. In view of the fact that these

FIGURE 1 Sites of Lodgment of 172 Arterial Emboli

diagnoses are often the least important of a group of major primary ones in a given case, it is probable that they are frequently not mentioned in the final list. It is certain, therefore, that the incidence of these particular emboli as listed is lower than the actual incidence. An examination of the diagnoses in the autopsy file during the same period shows an incidence of emboli to brain, spleen and kidney considerably higher than that derived from the

clinical study (Table 2). Like the clinical statistics, however, these figures cannot be considered representative of the whole picture, because they obviously do not include surgical and nonlethal emboli. In Bull's<sup>26</sup> material also the incidence of emboli to internal organs (such as the spleen and kidneys) at autopsy was higher than that in clinical figures.

The possible sources of arterial emboli have been listed by Agar<sup>26</sup> as pulmonary veins, mural thrombi in the heart, mitral-valve vegetations, atheromatous plaques in the aorta and, very rarely, the systemic veins or the right side of the heart through a patent interventricular septum or foramen ovale as originally described by Cohnheim.<sup>27</sup> To these Gross,<sup>28</sup> in a report on the occurrence of arterial emboli in children, has added thrombus from a closing ductus arteriosus. The embolus usually consists of a thrombus that has broken away from one of the sites described above. The possibility that emboli made up of fragments of tumor invade the large arteries or, more logically, the pulmonary veins, become detached and lodge in the periphery has long been postulated. That this actually occurs is shown in the interesting case reported by Groth<sup>29</sup> in which a sarcoma of the right hip traveled to the lung as a venous embolism and from there at a later date became an embolism to the left femoral artery. From here it and its very long propagating thrombus were removed surgically, and the leg was saved. Pathological examination of the amputated right leg, a specimen of tissue from the lung and the embolotomy specimen from the left femoral artery showed identical tumors. Emboli consisting of retained metallic projectiles have also been reported.<sup>30</sup>

The most common source of emboli is generally considered to be intracardiac. Danzis<sup>9</sup> states that 60 per cent are due to cardiac disease. Koucky et al.<sup>11</sup> state that 13 of their 25 patients had auricular fibrillation. Generally, the elucidation of etiologic factors has not been clear from the data presented. This has not been true in our study (Table 3), which shows that in 87 of the 98 patients, or 88.7 per cent, a clinical diagnosis could be made that gave presumptive evidence of a source of embolism within the heart (Fig 2). It is our impression from these observations that the presence or absence of a coronary occlusion, auricular fibrillation or bacterial endocarditis should offer a powerful argument for or against the diagnosis of arterial embolism, particularly since of the 11 patients with embolism from "undetermined" cause the records of 9 are not adequate to exclude any one or all of these etiologic factors. In only 2 patients did all the causes seem to be entirely excluded.

Since auricular fibrillation with presumably auricular thrombosis was the major cause of embolism it is of some interest to examine the causes of the fibrillation in these 64 cases (Table 4). It can be seen that rheumatic heart disease was responsible for about

two thirds of the cases of fibrillation and arteriosclerotic heart disease for the remainder. Although fibrillation due to thyrotoxicosis has been reported as causing emboli,<sup>22</sup> no such cases occurred in this series.

It has often been taught that drugs that restore a fibrillating auricle to normal rhythm may precipitate emboli. It is of interest that this sequence

patients with mural thrombi due to myocardial infarction was fifty-seven and two-thirds years, which is, as might be expected, slightly above the average. The average age of the 7 patients whose emboli were caused by bacterial endocarditis was forty-five and a half years, or slightly below the average. The average age of the 64 patients who suffered from emboli originating in auricular thrombi on the basis

of events could not be established in any of our patients.

### Sex and Age

The sex and age were determined in 97 of the 98 patients. There were 46 female and 51 male patients. The average age was fifty-two years, with extremes of twelve and seventy-seven years. The ages by decades are demonstrated in Figure 3. The youngest patient suffered a cerebral embolism from a subacute bacterial endocarditis superimposed on a congenital deformity described as the tetralogy of Fallot. The next youngest patient was twenty years of age, the embolism being caused by an auricu-

lar fibrillation was fifty-two years, or exactly at the over-all average. This group contained both the oldest and the next to the youngest patients. Table 4, which shows the basic heart disease in the patients with auricular fibrillation and demonstrates that only about two thirds of them suffered from rheumatic heart disease (most of the remainder having arteriosclerotic heart disease), explains the broad range of age in these patients.

The statistics from this study are similar to those reported by Petitpierre<sup>21</sup> in his group of 129 cases of embolism. He found the peak incidence in the fifth and sixth decades. There was a slight preponderance of female over male patients (a ratio of 63:51).

### Differential Diagnosis

In unoperated and unautopsied patients the diagnosis of embolism is always presumptive. It is for

this reason that most series that have been published deal solely with operative cases. Conditions that may be confused with emboli are chiefly two in number: arterial thrombosis and acute thrombophlebitis of the deep veins of an extremity. The former is much more frequent than the latter. In

acute arterial occlusion in a patient with arteriosclerosis, thrombosis, as pointed out by Linton,<sup>11</sup> can never be ruled out until direct observation of the vessel is made. In spite of the fact that the lodgment of an embolus is a severe vascular accident and according to most descriptions is accompanied

this differential diagnosis in difficult cases must not be persisted in too long. In doubtful cases it is better to err on the side of embolism, since therapy cannot wait upon academic proof.

The other condition that in rare but significant cases must be differentiated from embolism and from

FIGURE 2 Auricular Thrombosis

Photograph of the heart obtained at autopsy in a fifty-four-year-old man who, having had auricular fibrillation for eleven years due to rheumatic heart disease, entered the hospital in heart failure, from which he died eleven days later. Two episodes of arterial embolism occurred before death, one to the right popliteal artery one month before admission, and the other to the abdominal aorta two days before death.

by a sudden onset of severe pain, only 69 per cent of our patients experienced a sudden onset of emboli and only 55.8 per cent suffering from limb emboli had severe pain.

The site of the vascular occlusion is of some help in the differential diagnosis of the thrombosis.

Table 5 shows the location of 149 cases clinically diagnosed as arterial thromboses, excluding those of the coronary vessels, in 147 patients during the same period under study. The higher incidence of popliteal and mesenteric thrombosis in this table is of some significance in differentiating thrombosis from embolism. It has only a statistical value, however, since both popliteal embolism and acute femoral thrombosis occur in a significant number of cases. The clinical demonstration, or lack of it, of a source of embolism must chiefly be relied upon. As pointed out below, however, attempts to make

thrombosis as well as acute thrombophlebitis. As shown by Leriche and Kunlin,<sup>17</sup> Danzis,<sup>9</sup> Edwards,<sup>12</sup> Ochsner and DeBakey<sup>34</sup> and Fontaine and Forster,<sup>35</sup> massive blockage of the deep venous spaces of the leg may throw the arteries into such a degree of spasm that the palpable pulses can disappear. A suggestive line of skin demarcation can ensue and even lead to gangrene. Careful inspection of the

FIGURE 3 Incidence of Arterial Emboli according to Decades

limb for venous engorgement, lack of muscular paralysis and anesthesia and the use of an oscillometer or aneroid sphygmomanometer to detect the presence or absence of oscillation in the calf will make this differential diagnosis.

## EMBOLISM TO LIMB ARTERIES

The object of this section is to discuss the prognosis without treatment of arterial emboli to the major limb arteries, the types of treatment available and the results of these methods in the hands of others and in our own. Table 6 gives a composite view of our results.

## Results with No Treatment

It is generally conceded that arterial emboli to the upper limb that are untreated carry a better prognosis than those to the lower limb.<sup>4, 12</sup> The cor-

TABLE 5 Sites of Acute Arterial Thromboses in 147 Patients (Coronary Thrombosis Excluded)

rect figures are difficult to obtain, particularly from recent studies, since in all cases at present some form

of treatment was necessary other than amputation if the result had been unfavorable or mere treatment of the basic cardiac disease if it had been favorable.

The rate of limbs saved without treatment seems high. One might say that this figure compares favorably with some statistics on operative results. An important consideration is that in the majority of patients who received no treatment the emboli were to the upper extremity, where the prognosis is known to be better than that in the lower limb. In 23 analyzable cases affecting the upper limb 14 received no treatment, in these cases all limbs were saved. In the lower limb among 24 analyzable cases with no treatment limbs were saved in only 7, and were lost in 17. Thus, the 55.2 per cent salvage for all limbs under no treatment is reduced to 29.1 per cent if only the lower limbs are considered.

## Results with Conservative Treatment

Conservative treatment was available during the whole ten-year period. In 1937 and 1938 the principal conservative methods used were papaverine,<sup>22</sup> paravertebral novocain block<sup>17</sup> and the Pavacex boot for the administration of intermittent suction and pressure.<sup>18</sup> After 1939 the Pavacex boot gave place largely to intermittent venous occlusion and the oscillating bed. The use of the other conservative methods was continued.

Our results are drawn from 38 analyzable cases in which 25 limbs, or 65.8 per cent, were saved by these

\*The total number of cases in which no treatment was given was 47, of which 38 were analyzable and in which 21 limbs (55.2 per cent) were saved. The total number of cases in which conservative treatment was given was 38, of which 38 were analyzable and in which 25 limbs (65.8 per cent) were saved. Operation was performed in 25 cases, of which 21 were analyzable and in which 18 limbs (85.7 per cent) were saved.

of treatment is used. In our cases 110 emboli involved the extremities. Thirteen of these are not suitable for evaluation of treatment since the patients died too soon after admission. Of the remaining 97, 38 received no treatment, and only 21 (55.2 per cent) of limbs were saved. To evaluate fairly these figures, it must be stated that the reason these patients received no treatment was that they were admitted to the hospital so late that the fate of the limb had already been decided by the time they were first observed. No treatment, there-

fore, was necessary other than amputation if the result had been unfavorable or mere treatment of the basic cardiac disease if it had been favorable.

An attempt to evaluate individually the various available forms of nonoperative treatment from our records was fruitless. Most often they were used in combination. The reputation of none of the methods is unblemished by the loss of one or more limbs during or after its use. Heparin, for instance,

was used in 9 cases. The limbs were saved in 5 and lost in 4, in some of the former the drug was employed as a last resort, and in some of the latter the limbs might have been saved without it. On theoretical grounds the use of these adjuncts in patients on whom surgery is impossible or who are waiting for surgery or have had unsuccessful surgery seems logical. Paravertebral block relaxes spasm and opens collateral vessels, and heparin should prevent the distal propagating thrombus. Although there is conflicting evidence concerning the value of inter-

hours<sup>39</sup> — the results in patients who have been operated upon within a very few hours of onset are far better than in those having later operations. The value of statistics must be criticized with this factor in mind.

Table 7 shows the results of surgical treatment gleaned from several series in the literature. The favorable results range between 25 and 50 per cent in the larger series and considerably higher in two smaller series, if one does not exclude patients whose limbs were saved but who died in the hos-

†Many patients the same as those of Petitpierre, but series not identical.

mittent venous occlusion<sup>36, 37</sup> and passive vascular exercises our clinical impression has been that these are the most valuable adjuncts of all.

The conservative weapon that we have found least useful has been papaverine. Clinical observations have revealed little benefit from this drug other than a certain amount of pain relief. The experimental work of Abramson<sup>38</sup> and others has shown that this drug produces little improvement in the vascular responses in the limbs.

### Results of Surgical Treatment

A review of the literature reveals that the overall results of embolectomy are disappointing if one wishes to set up as a goal the ideal of 100 per cent survival of limbs and patients. There is as yet little that can be done about patients who die of heart failure or cerebral embolism. We should, however, be able to save 100 per cent of limbs. Since the muscles of a limb can survive complete lack of oxygen for only a limited time — perhaps six to ten

hours of primary heart disease. Some authors argue that surgery in patients who are soon to die of their primary disease is not worth while. There is no question, however, that the prevention of gangrene can spare the patient much suffering. In addition, it is not always possible at a given point during the acute stage of the disease to separate the doomed patients from those destined to survive.

The following analysis of our surgical results is given. Twenty-one patients were operated upon for removal of emboli. Twenty-five operations were performed, 4 patients having two operations each, the second operation being done for occurrence of emboli either at a new site or at the old one.

Four of these emboli were in 3 patients who died so soon that the effect of operation on the limbs could not be determined. Of 21 analyzable limbs, 18 or 85.7 per cent, survived.

In the 3 cases in which the limbs were lost there was technical difficulty in removing the embolus in 2 cases because the clot was adherent to the artery.

There was difficulty in the other case because of inability to remove all the clot satisfactorily from an embolus at the aortic bifurcation through bilateral femoral incisions. The elapsed time from onset to embolectomy in the former 2 cases was nine and a half and seventeen hours, and in the latter three hours.

### Mortality and Causes of Death

A total of 38 of the 98 patients died in the hospital, a mortality of 38.7 per cent (Table 8). All patients died of cardiovascular disease. The surgically treated patients showed a mortality of 28.6 per cent, the rate for the nonsurgically treated cases, therefore, being somewhat above the average. The mortality figures from other clinics where the emboli of major peripheral arteries are treated surgically are higher (Petitpierre,<sup>1</sup> 50 per cent, Nyström,<sup>7</sup> 60 per cent, and Strömbeck,<sup>40</sup> 63 per cent).

We consider these results to demonstrate that surgery itself is usually not harmful. Exceptions to this statement may be that operation on the abdominal aorta, since it cannot be done under local anesthesia, is poorly tolerated by the desperately ill patient, that operation on the popliteal artery is technically so difficult to perform without injury to collateral vessels or constriction of the small bifurcation of the artery by the suture line that conservative treatment is regarded as the one of choice, and that in a patient with very advanced peripheral arteriosclerosis the likelihood of thrombosis at the arteriotomy suture line after embolectomy is great, since the next traumatic suturing of an irregularly calcified arterial wall may be impossible—in such a patient, therefore, surgery may be decided against on this basis. The 1 death in this series that could possibly be attributed to surgery occurred on the operating table in collapse of a very sick forty-year-old woman with rheumatic heart disease who had just had an embolus removed from the aorta. Surgery should not be condemned on the basis of such a case, however, since 2 patients in the group died under similar circumstances on the way to the operating room before any anesthesia had been given or incision made.

### Time Factor in the Treatment of Embolism

The speed with which the patient is brought to the surgeon after the embolism has struck is known to be of the utmost importance. Key considered ten hours to be the period chosen as a dividing line between favorable and unfavorable results. Table 7 shows that in the experience of others this figure has remained the best approximation available. Experimental evidence also suggests that it is accurate.<sup>39</sup>

The average elapsed time from onset to surgery in the 16 patients whose limbs survived was eight

and three-quarter hours. The longest elapsed time was eleven hours, except in a case in which a femoral embolism was removed sixty hours after onset, in this patient a pregangrenous state of two toes was converted into a viable foot by the procedure, pulses that had previously been absent actually returning to the foot. Although successful late embolectomy has been reported by Hopkins<sup>38</sup> and others, it is the exception rather than the rule that an embolus that has been lodged for this length of time is not so adherent that it cannot be removed.

TABLE 8 Hospital Mortality and Cause of Death in 98 Patients with Arterial Embolism

CAUSE OF DEATH	SURGICAL CASES	NONSURGICAL CASES	TOTAL
Cerebral embolism	—	14	14
Cardiac failure	5	5	10
Myocardial infarction	—	6	7
Myocardial infarction	—	4	4

Unknown	—	1	1
Totals	6 (28.6%)*	32 (41.5%)+	38 (38.7%)

\*Of 21 cases.

+Of 77 cases.

Surgery should not necessarily be abandoned in peripheral embolism because a temporal "deadline" has been passed. Much, of course, depends on the appearance of the limb. If actual gangrene has set in as may happen within two days, embolectomy is not to be considered. If, however, there is calf paralysis, foot anesthesia and marked vasospasm with a line of demarcation that is suggestive only, embolectomy followed by conservative supportive measures should be performed.

### Late Results

When a patient presents himself with an acute arterial occlusion, efforts are primarily directed at saving the limb. It has been shown<sup>40</sup> that even if the tissues of the limb survive complete arterial occlusion there is a likelihood of future difficulty with proper mechanics of the member if the main arterial trunk is allowed to remain obstructed. Strömbeck<sup>40</sup> has left a very complete report on the follow-up examination of a large number of patients. Of the 327 patients, 61 were discharged from the hospital after successful peripheral-artery embolectomy. Of these 61, three fourths lived for one year, half lived for three years, a third lived for five years, and one eighth lived for ten years. At the time of the report 41 patients had died. The cause of death in 20 of these was heart failure in 12 cases was caused by hemiplegia presumably due to embolism to the brain. Strömbeck also mentions that half the patients seen on follow-up study with

limbs that had been saved had numbness or paresthesias

Some fragmentary data are available on 9 of our 14 patients who underwent embolectomy and survived. Of these, 6 have died, 3 of cerebral embolism, 1 of coronary closure, 1 of heart failure and 1 of carcinoma of the esophagus. Of the 3 patients living, 1 had a cerebral embolism with hemiplegia and the further course is unknown. Two others were living and well three and seven years, respectively, after operation.

There is also some information on 10 of the 44 patients who survived nonsurgical treatment. Five remained or became hemiplegic. One of these was well for seven years before dying of cerebral embolism. Another patient died two days after discharge, and another three years after discharge of coronary occlusion. Three patients were living in fair health two years after discharge.

### DISCUSSION

The treatment of arterial embolism is always undertaken as an emergency. It is a nonelective procedure. Patients cannot be referred at leisure to faraway specialists for this treatment. Every community where human beings suffer from rheumatic fever or arteriosclerosis will observe a regular, though small, incidence of arterial embolism. Any doctor, whatever his specialty, might be the nearest to a patient so stricken and be called upon to provide at least first aid. Immediate hospitalization and initiation of definitive treatment should be urged. This treatment does not have a fair chance unless the time factor is considered as paramount. Nystrom<sup>7</sup> has pointed out the benefits to be derived if the whole medical community participates in the treatment of these patients. From our study we have formed the opinion that operation should be performed in all cases in which local anesthesia can be used, with the sole exception of popliteal emboli. Also, aortic embolectomy, which requires a general anesthetic, is the treatment of choice for embolism of the aorta. Conservative treatment, although its results are good in some cases, is justifiable only when the embolism obviously does not endanger the limb, in the rare aortic embolism in which the patient cannot be brought into the proper condition to withstand a general anesthetic, and in popliteal embolism. It is emphasized that if one is forced to use conservative therapy alone it is essential that it be initiated with as much dispatch and urgency as is advocated for surgical treatment. Even though the embolism is for many patients the last milestone on the downward road of serious cardiac disease, lives are saved by embolectomy. It is difficult to doubt the value of the procedure when one reads case reports such as that contributed by Ravdin and Wood<sup>44</sup> in which a young man was reclaimed by aortic embolectomy for a very useful existence. Danzis<sup>9</sup> has said "While the operative

results are far from ideal, much suffering may be spared and many limbs and even lives be saved by prompt intervention and careful surgical technique."

### SUMMARY

A review of 179 arterial emboli in 98 patients is presented. One hundred and ten involved the limbs.

The salvage of 85.7 per cent of 21 limbs, which could be analyzed after embolectomy, is reported.

In 65.8 per cent of conservatively treated arterial emboli, the limb was preserved.

It is concluded that although available conservative weapons are valuable adjuncts to surgery, surgical embolectomy is the treatment of choice in peripheral-artery embolism.

## IDIOPATHIC HYPERLIPEMIA\*

WINTHROP C. HOPGOOD, M.D.†

FRAMINGHAM, MASSACHUSETTS

**I**DIOPATHIC hyperlipemia, an apparently benign disorder of neutral fat metabolism of unknown etiology, has been reported six times since Buerger and Grütz<sup>1</sup> first described the syndrome in 1932. Thannhauser<sup>2</sup> reviewed the reported cases to the time of the publication of his monograph in 1940. The essential features of this disorder consist of a grossly milky blood serum due to increase in neutral fat content, together with enlargement of the liver and spleen. Xanthomatous lesions of the skin may also be present. Unexplained abdominal colic has occurred in half the cases. A moderate reduction in blood fats has followed dietary treatment, but normal values have not resulted.

### CASE REPORT

H. L., a 26-year-old married veteran was admitted to the hospital on December 11, 1946, because of a chronic, non-productive cough of 10 years' duration. This had become severer after an attack of bronchitis in the preceding July. He had had no other symptoms of any sort.

In early childhood skin lesions, which had extended a yellow matter, had developed on the legs, and later between the ages of 9 and 10, yellow plaques had appeared on the extremities. In 1944 while in Italy the patient had experienced several brief episodes of cramp-like pain in the middle and upper abdomen, accompanied by nausea and vomiting. During hospitalization for these attacks lipemia and splenomegaly were first discovered. After prolonged study he was discharged from the Army. Since then he had remained free of gastrointestinal complaints.

His mother and three siblings were living and well. His father had died of cancer of the bowel. There was no family history of diabetes mellitus or other metabolic disease.

Physical examination disclosed a well-nourished man who was 5 feet 2.5 inches tall and who weighed 125 pounds. The skin and mucous membranes were normal and there were no xanthomatous lesions. Examination of the heart revealed a

soft systolic murmur in the pulmonary area which disappeared on deep inspiration. The lungs were clear and resonant; the abdomen was soft and no tenderness was elicited. A firm liver edge was palpable 2 cm. below the right costal margin in the midclavicular line. The edge of the spleen was easily palpated 6 cm. below the left costal margin. Rectal examination showed external hemorrhoidal tags. The remainder of the examination was within normal limits.

The temperature, pulse and respirations were normal. The blood pressure was 120/80.

Examination of the blood disclosed a red-cell count of 4,900,000 with a hemoglobin of 14 gm. per 100 cc. and a white-cell count of 4,300 with 57 per cent segmented neutrophils, 4 per cent band forms, 36 per cent lymphocytes and 3 per cent monocytes. The urine had a specific gravity of 1.025 and gave a + in + test for albumin and a + reduction of Benedict's solution. The reaction was acid. No Bence-Jones protein was present. Microscopic examination of the sediment was negative. The serum cholesterol was 295 mg. and subsequently 205 mg. per 100 cc. after the patient had been on a fat free diet for 48 hours. The serum bilirubin was less than 0.1 mg. per 100 cc. The alkaline phosphatase was 3.5 Bodansky units. The cephalin flocculation test was + after 48 hours; the fasting blood sugar was 106 mg. per 100 cc. and the prothrombin time 88 per cent of normal; the total protein was 7 gm. per 100 cc., with 3.9 gm. of albumin and 3.1 gm. of globulin. Hemolysis of the erythrocytes began at 0.46 per cent sodium chloride and was complete at 0.38 per cent. The coagulation time was 6 minutes and the bleeding time was 1 minute. A stool was negative for occult blood. The vital capacity was 3800 cc.

A ray film of the skull, chest, spine, long bones and sinuses were normal. An intravenous pyelogram showed the left kidney to be rotated on its longitudinal axis and displaced slightly toward the midline by the enlarged spleen; the contrast substance was excreted to a normal degree and no abnormalities were noted in the urinary tract.

On symptomatic treatment the cough, presumed to be due to chronic bronchitis, disappeared and the patient was discharged on January 2, 1947, without dietary or other restrictions. On February 17 he returned for a blood lipid determination (Table 1) and immediately thereafter he began to suffer from malaise, anorexia, headache, chills and fever.

Physical examination revealed herpes simplex on the lip; otherwise the findings were unchanged from admission.

\*From the Medical Service, Cushing Veterans Administration Hospital.  
†Resident physician, Medical Service, Cushing Veterans Administration Hospital.

The temperature was 100.2°F, the pulse 96, and the respirations 16.

Examination of the blood showed a red-cell count of 4,100,000, with a hemoglobin of 13.4 gm per 100 cc, and a white-cell count of 2410, with 32 per cent segmented neutrophils, 18 per cent band forms, 38 per cent lymphocytes and 12 per cent monocytes. The urine gave a ++ test for albumin and contained no sugar. The sediment was normal. Blood smears were negative for malaria. Blood cultures were sterile. No cold agglutinins were present in the blood serum. An x-ray film of the chest showed no change.

Four days after entry the patient became icteric, and the liver edge extended 10 cm below the right costal margin. The stools became light colored, and the urine became dark, with a positive test for bile. The urinary urobilinogen was 1.8 Ehrlich units in 2 hours, the serum bilirubin 7.8 mg per 100 cc total, with a positive direct van den Bergh reaction, and the cephalin flocculation ++++. The white-cell count

disease<sup>5</sup> revealed no cause for abdominal pain. The history in the case presented above indicates that the patient had had such a pain in Italy in 1944.

Hepatic and splenic enlargement, varying in degree, has been uniformly observed in all the reported cases of idiopathic hyperlipemia. In Holt's patient the organs enlarged after each attack of abdominal pain at the same time that the blood lipids decreased. In 3 cases a decrease in hepatosplenomegaly occurred with the restriction of fat in the diet.

Whether patients with idiopathic hyperlipemia subsequently develop xanthomatous biliary cirrhosis is not known. None of the reported cases of idio-

TABLE 1 Blood Lipids in a Case of Idiopathic Hyperlipemia \*

February 17†	3370	3202	328	290	250	100
April 30‡	1840	1612	207	—	204	118
July 7†	3730	3420	273	—	290	165

\*Analyses performed by Dr Siegfried J Thannhauser.

†Normal diet.

‡Low-fat diet.

fell to 2000, with 36 per cent segmented neutrophils and 64 per cent lymphocytes.

The patient was placed on a high-carbohydrate, high-protein, low-fat (30 gm) diet. His appetite rapidly returned, and after 6 weeks of bed rest, the serum van den Bergh, cephalin flocculation and urine urobilinogen had returned to normal. Repeated urinary specimens were bile free, but showed a + to +++ test for albumin and a + to +++ reduction of Benedict's reagent. Glucose (100 gm) was administered by mouth. The fasting blood sugar was 85 mg per 100 cc, and at ½ hour, 1 hour, 2 hours and 3 hours, respectively, 162, 128, 86 and 68 mg per 100 cc. The urine gave —, + (olive) + + + (orange) + + (yellow) and — reductions of Benedict's solution in the fasting, ½-hour, 1-hour, 2-hour and 3-hour specimens, respectively. The serum amylase was 11 units per 100 cc.

The patient was discharged on April 4, with instructions to continue the rigid low-fat diet. After a total of 9 weeks on this regimen, the serum lipids showed a marked decrease (Table 1).

On July 7 he reported that he felt perfectly well, but had not been following his diet rigidly. The serum lipids had returned to the original level (Table 1).

Two siblings of the patient were examined, the blood serum of neither was lipemic.

## DISCUSSION

Skin lesions have been observed in 4 of the 6 previously reported cases of idiopathic hyperlipemia. Three patients had yellowish, discrete papules, chiefly on the extensor surfaces of the extremities and on the buttocks. These lesions are also found on the lips, face, palate, eyelids, ears, fingers, toes and scrotum. One patient had a somewhat different type of lesion beginning as vesicles, which soon ruptured, leaving shallow ulcers that persisted for a number of months.<sup>3,4</sup> The history of the patient reported above suggests that he had had both types of lesions in childhood, although the skin was free of xanthomatous lesions during observation.

Colicky abdominal pain has been reported in 3 cases. Exploratory laparotomy in 1 case<sup>3,4</sup> and autopsy in a patient who died of an intercurrent

pathic hyperlipemia have exhibited jaundice. The jaundice in the case reported above is believed to have been a simple infectious hepatitis. In xanthomatous biliary cirrhosis neutral fat is not elevated to the degree reported in idiopathic hyperlipemia, and there is a disproportionate rise in the total cholesterol.

Chronic pancreatitis may be associated with hyperlipemia as well as diabetes mellitus. In many cases the attacks of abdominal pain associated with pancreatitis do not appear differentiable from the pain noted in idiopathic hyperlipemia. It is possible that chronic pancreatic disease is related etiologically to idiopathic hyperlipemia. However, in the only autopsied case of this disorder a normal pancreas was observed.<sup>6</sup>

The prognosis in this condition appears to be excellent. Treatment with lecithin, choline, thyroxin, insulin, liver extract, anterior pituitary extract and lipocain has not significantly altered the blood fats.<sup>1</sup> A low-fat intake has led to reduced blood fat levels, a subsidence of skin lesions and a decrease in the size of the spleen and liver.

## SUMMARY

A case of idiopathic hyperlipemia with hepatosplenomegaly is reported. The findings in the 6 cases of this disorder previously described are reviewed.

## STREPTOMYCIN TREATMENT IN ACUTE BRUCELLOSIS\*

## Report of a Case with Review of the Literature

CALDERON HOWE, M.D.,† AND JAMES T. HEYL, M.D.‡

BOSTON

ALL three strains of *Brucella* are known to be sensitive to small concentrations of streptomycin in vitro.<sup>1</sup> This antibiotic has also been shown to protect chick embryos against infection with *Brucella abortus*<sup>2</sup> and to modify the infection to a considerable degree in guinea pigs.<sup>4</sup> Recent studies, however, throw doubt on the efficacy of streptomycin in experimental brucellosis in guinea pigs.<sup>4</sup> The reports that have appeared on the use

with bacteremia gave evidence of improvement, after three separate courses of streptomycin, the last course following splenectomy. Reimann, Price and Elias<sup>3</sup> give data on 3 cases of brucellosis. Fever in the first 2 cases appeared to respond temporarily to streptomycin administration, the third case showed no response. In these cases, no blood cultures were taken during or after treatment and the length of the follow-up period is not specified.

TABLE I Significant Data in Cases of *Brucella* Treated with Streptomycin

of streptomycin in the treatment of brucellosis in human beings have so far been equally inconclusive.

Table I lists the significant data on streptomycin treatment in the cases reported in the literature. Reports in which neither blood levels nor daily dosage of streptomycin are clearly specified are not included.

Of the 45 cases of brucellosis reported by Keefer,<sup>4</sup> 30 showed decrease in fever, and 15 showed no response to streptomycin treatment. The incidence of relapse in these cases is not given. Nichols and Herrell<sup>4, 7</sup> have reported 11 cases of brucellosis, giving details in only 3. Only 1 of the patients

Morgan and Hunt<sup>8</sup> present 1 case in which there was no clear-cut clinical response, despite temporary elimination of organisms from the blood stream. Pulaski and Amspacher,<sup>10</sup> in treating 8 patients with bacteremia due to *Brucella*, noted benefit in only 2 cases in which sulfadiazine was given concomitantly, and recommend this combined type of therapy in the treatment of brucellosis. Howe et al.<sup>11</sup> used streptomycin in 3 cases of acute brucellosis without appreciable change in any, 2 cases had relapses after treatment. Hall, Braude and Spink,<sup>12, 13</sup> in 2 cases of chronic brucellosis with bacteremia, claimed no clear-cut effect from streptomycin. In a third case, with endocarditis, these authors noted that organisms recovered during and after thirty-one days' treatment with streptomycin had developed marked resistance to the drug in vitro.

In 2 additional cases, in which high blood levels were attained, these authors report improvement as a result of therapy. In 2 cases reported as brucellosis by Goetz<sup>14</sup> and Brier,<sup>15</sup> the diagnosis was inconclusive. A definite impression of the effect of streptomycin in the 6 cases of acute brucellosis reported by Finch<sup>16</sup> cannot be gained from the data presented, although a favorable response to treatment is said to have been obtained.

Because of the equivocal results observed to date, it seems worth while to present 1 more case of

chemotherapy, showed no abnormalities. Blood cultures were taken into liver infusion and tryptic digest broth, and were incubated at 37°C in candle jars (approximately 10 per cent carbon dioxide), none being discarded as negative before the end of 3 weeks. Thioglycollate was added to the cultures taken during the period in which the patient was receiving streptomycin. The increased carbon dioxide tension may also have served to reduce the action in vitro of what little streptomycin was added to the cultures with the patient's blood.<sup>1</sup> *Br. abortus* was recovered from the blood on numerous occasions prior to streptomycin therapy, and the strain was identified by growth on differential dye mediums and estimate of hydrogen sulfide production. During and after treatment, all blood cultures remained sterile. The strain was found to be sensitive, in vitro, to 2.0 microgm.

FIGURE 1 Data in Case of Acute Brucellosis

Ten months after the onset of the illness and eight months after completion of treatment, blood cultures were negative, and the agglutination titer was 1:640. The patient remained well up to fifteen months after treatment.

infection due to *Br. abortus*, in which streptomycin was used with some evidence of therapeutic effect.

### CASE REPORT

A 52-year-old man, whose past medical history was not remarkable, was admitted to the hospital on October 19, 1946, 3 weeks after the onset of extreme malaise, anorexia, slight nasal congestion and dry cough. Two weeks before admission, he had had a shaking chill, which was followed by daily afternoon temperature elevations to 100 to 102°F and profuse night sweats. He had consumed unpasteurized milk on numerous occasions prior to the onset of the illness. A blood specimen sent to the Massachusetts Department of Public Health 1 week before admission had shown a titer of agglutinins for *Br. suis* of 1:400, rising 4 days before admission to 1:5000. A presumptive diagnosis of brucellosis had therefore been made by the family physician.\*

Physical examination showed a patient who appeared to be exhausted and was perspiring profusely. The mucous membranes were pale. The liver was palpable three finger-breadths below the right costal margin. The spleen was not felt at any time during the period of the patient's hospitalization. Physical examination was otherwise negative.

The temperature was 101°F by rectum, the pulse 88, and the respirations 20. The blood pressure was 100/70.

Examination of the blood revealed a hemoglobin of 15 gm per 100 cc. and a hematocrit of 45, falling to 39 during the ensuing month. The blood Hinton test was negative. The sedimentation rate varied between 14 and 16 mm per minute (Wintrobe method) as determined on five occasions. The white-cell count was consistently found to be between 5000 and 6000, with 40 to 50 per cent lymphocytes. The urine on admission, as well as on four occasions during

of streptomycin per cubic centimeter of tryptic digest broth. The variations in the titer of agglutinins for *Br. abortus* are shown in Figure 1.

The course of the fever was typical of acute brucellosis. Streptomycin did not become available for use in this case until 5 weeks after admission, and a control period of observation in which no chemotherapeutic or antipyretic agents were administered was thus allowed. Fifty-eight days after the onset of the illness, a course of streptomycin was started.† The patient was given a total of 60 gm, in daily doses of 6 gm (1 gm every 4 hours), over a period of 10 days. He complained of increasingly acute burning, aching and tender swelling at the sites of intramuscular injections, despite the presence of procaine in the injected solutions of streptomycin. By the 4th day of treatment, because of excruciating pain in both gluteal and quadriceps muscle groups, the patient was hardly able to walk, was acutely uncomfortable in any position in bed and was unable to sleep despite sedation. The mode of administration of the drug was therefore altered, so that he received 1 gm intravenously every 4 hours during the day, each dose being dissolved in 400 cc of physiologic saline solution and given over approximately ½ hour, only the midnight and 4-a.m. doses were given intramuscularly as before. This change had no appreciable effect on the established blood levels of streptomycin. Determinations were made shortly before and 1 hour after scheduled intramuscular intravenous doses, to ascertain the minimum and maximum blood concentrations obtained by each route. The blood levels varied between 20 and 25 microgm per cubic centimeter of blood.

During the last 5 days of treatment, the temperature declined rapidly. The patient felt much improved, he suffered no more night sweats, his appetite increased, and the muscle soreness subsided promptly. Audiograms and vestibular-function tests were normal at the conclusion of

\*We are indebted to Dr. F. F. Blumenthal, of Bridgewater, Massachusetts, for referring the patient to this hospital, and for his continued interest and co-operation.

†Streptomycin hydrochloride kindly supplied by Merck and Company, Rahway, New Jersey.

treatment, except for slight high tone deafness. During the first few weeks of convalescence, he complained of definite unsteadiness of gait, occasional dizziness and questionable tinnitus, all of which may have been due to streptomycin toxicity. For approximately 8 months after the completion of therapy the patient continued to improve generally. He returned to work, and had no sign of recurrence of the infection. The vestibular symptoms diminished, but persisted in a minimal degree. On July 27, 1947, 10 months after the onset of illness and 8 months after the beginning of treatment, blood cultures were sterile and the agglutinin titer was 1:640. Fifteen months after treatment the patient was still free of symptoms.

### Discussion

In untreated cases of acute brucellosis, the degree to which recovery takes place is directly related to the efficiency of the individual immune mechanism. In the case presented above, the effect of streptomycin treatment was added to that of the immune response. Both these factors should therefore be considered in any attempt to explain the recovery.

Such an attempt is complicated by the nature of the disease, since, in the light of recent studies by Ruiz-Castaneda<sup>17</sup> confirming earlier observations of Smith,<sup>18</sup> Goodpasture and Anderson<sup>19</sup> and Buddingh and Womack,<sup>20</sup> brucellosis appears to be predominantly an intracellular infection. Meyer<sup>21</sup> has stated more specifically that "selective intracellular parasitism in mesenchyme cells of various organs is of greatest significance in the pathogenesis of Brucella infections." The titer of specific agglutinins by present methods of determination is probably the result of several constantly changing forces: the degree of host parasitization, or the total amount of antigen present, which is affected to a varying extent by the bactericidal power of the blood, the rate of production and total quantity of antibody, and the degree to which antigen and antibody react with each other within the host. A rapidly mounting increment of organisms, multiplying intracellularly and outstripping the production of antibody with which to neutralize circulating antigen, might be evidenced by a declining concentration of agglutinins. Conversely, with the curtailment of bacteremia, either spontaneously or by chemotherapy as in the case reported above, there is presumably some limitation of further host parasitization, and the agglutinin titer might be expected to rise if the immune response continues. A definite fall in agglutinin titer was observed during the first seven weeks of the patient's illness, and shortly after his abrupt clinical recovery, the titer started to rise again. It is possible that chemotherapy at the end of the eighth week of continued bacteremia spared this patient a more protracted course and allowed his own immune mechanism to become effective. However, the fact that resistance to and recovery from infection is not wholly dependent upon the presence of tangible antibody—that is, agglutinins—and must involve other less readily detectable immune factors is attested by the coexistence in the blood of organisms and circulating antibody, not only in brucellosis but also in other infectious

diseases, such as typhoid fever and subacute bacterial endocarditis.

That streptomycin penetrates beyond the cell membrane is suggested by reports on the concentration of the drug in various tissues after its parenteral administration in man<sup>22</sup> and animals.<sup>23</sup> It is thus not illogical to suppose that in the presence of sufficiently high blood concentrations, maintained for adequate periods, streptomycin exerts bacteriostatic or bactericidal action on intracellular organisms. It may be significant that among previously reported cases of brucellosis in which it was possible to decide whether streptomycin treatment had been effective, temporary or lasting benefit was demonstrated only in patients in whom the blood levels reached or exceeded 20 to 30 microgm per cubic centimeter or in whom the daily dose at any time approached 6 gm. It is of interest in this connection that the patient described above received 6 gm a day for ten days, maintaining blood levels between 20 and 25 microgm per cubic centimeter and recovered completely, albeit with minimal signs of streptomycin toxicity. It is probable, however, that the effect of antibiotics on intracellular infections is not all a simple matter of dosage and blood levels, since tularemia, also primarily an intracellular infection, is far more susceptible of cure with streptomycin than brucellosis appears to be.

### SUMMARY

An acute case of brucellosis, in which streptomycin was given in large doses, with apparent success, is presented in detail. In a review of all previously reported cases of brucellosis treated with this antibiotic, it appears that patients in whom the highest blood levels of drug were maintained for even relatively short periods showed more signs of response than those in whom lower blood levels were maintained over relatively longer periods. Therapy at high dosage, however, is not without risk of streptomycin intoxication, as evidenced by the slight though definite vestibular impairment persisting in the case reported.

## THE VALUE OF A SPECIAL AURICULAR LEAD AND OF CAROTID-SINUS PRESSURE IN THE ELECTROCARDIOGRAPHIC DIAGNOSIS OF TACHYCARDIAS AND OTHER DISORDERS OF THE HEART BEAT\*

LAURENCE B ELLIS, M D,† LESLIE W LANNAN‡ AND JAMES M FAULKNER, M D§

BOSTON

ONE of the chief uses of the electrocardiogram in clinical medicine is in the differential diagnosis of cardiac arrhythmias. Ordinarily, a definite diagnosis of the disorder of the beat can be made easily from the standard leads, but in patients with tachycardias it may be difficult or impossible to be certain of the type of arrhythmia present because the auricular waves may be small or hidden in the QRS or T complexes. The same statement is occasionally true with slower rates. Hence, a lead in which the electrodes are so applied as to show maximal potential changes developed by auricular activity may be of help under such circumstances.

Lewis<sup>1</sup> first noticed in 1910 that the F waves of auricular fibrillation were best brought out in electrocardiograms in which the exploring electrodes were placed over the region of the right auricle. Later, Ackermann<sup>2</sup> demonstrated that the auricular waves were well defined when needle electrodes were placed in the second and fifth interspaces to the right of the sternum. Subsequently, many studies have been made, many of which have dealt with distinguishing the activity of the two auricles, a problem with which we are not here concerned. Luisada<sup>3</sup> has summarized knowledge of auricular leads and of auricular disorders. Among these studies an important advance was made in 1934 by Lieberman and Lieberman,<sup>4</sup> who introduced the technic of the esophageal lead. This has been utilized frequently since then for auricular disorders but especially in the diagnosis of posterior myocardial infarction. Recently, Butterworth and Poindexter<sup>5</sup> have em-

phasized the value of the esophageal lead in clinical electrocardiography in the diagnosis of tachycardias and arrhythmias.

In January, 1937, the employment of a special auricular lead was first introduced at the Boston City Hospital by one of us (J M F). In the succeeding ten years this lead has been routinely employed, often in combination with carotid-sinus pressure, when the type of rhythm was not clear. During this period the procedure has been carried out about 2600 times, which represents 4.3 per cent of the total of 60,000 records taken. Our procedure has consisted in taking electrocardiograms by the usual technic including routine precordial leads. In addition, we have obtained the special auricular lead by removing the electrode from the left arm and placing it on the chest in the third interspace just to the right of the sternum. Tracings are then taken with the control switch successively at Leads I and 3. This has given records that are CR and inverted CF (labeled in the illustrations as CF'). It has been found that the auricular waves are seen best sometimes in one and sometimes in the other lead. Since we have not been concerned in this lead with the details of contour of the P waves or other complexes, the inverted CF lead has been no disadvantage and technically has been a more rapid and simple procedure than a CF lead taken in the conventional way.

In addition, while these leads are being taken pressure has been applied alternately to the right and left carotid sinuses or to both at once. Although it is well known that such vagal stimulation may abolish certain paroxysmal tachycardias or produce a temporary increase in auriculoventricular block in auricular flutter and tachycardia, thus making it easier to make an electrocardiographic diagnosis, it seems to be less widely appreciated that this maneuver may cause a very slight transitory slowing in

cedure Although the esophageal lead is probably, the best for the elucidation of auricular activity in P waves The discussion, however, is usually confined to a single arrhythmia such as auricular flutter

and is easily overlooked, and the wide usefulness of the lead is not emphasized. It is certainly clear that the majority of physicians who are doing electrocardiography are unaware of the value of this procedure. Whether the conventional CR<sub>1</sub> or CF<sub>1</sub> would reveal as much information concerning auricular activity as the auricular lead is not evident from this study, since such leads have not been taken continually in this laboratory.

### SUMMARY

A special electrocardiographic lead that has proved of value in the identification of auricular activity is described. This consists of the placement of the left arm electrode over the third interspace

to the right of the sternum and taking the electrocardiographic tracings successively in Leads 1 and 3. At the same time the application of carotid-sinus pressure is carried out. This procedure is useful in routine clinical electrocardiography in the diagnosis of tachycardias and of other arrhythmias when the P waves are not readily evident.

#### Metabolic Changes

Clinical reports as well as chemical studies emphasize certain new features in diabetic acidosis. The case report of Holler<sup>12</sup> showed that it is possible for a patient in diabetic acidosis to develop a critically low level of potassium in the blood serum, with paralysis of respiration that may be relieved by the administration of a potassium-containing solution.

Martin and Wertman<sup>14</sup> have analyzed serial measurements of the serum potassium, magnesium and calcium concentrations in 14 patients with diabetic acidosis (carbon dioxide combining power below 9 milliequiv. per liter). Three patients were comatose on admission, 3 were semicomatose, and 8 were conscious, 1 patient, admitted in coma, died. In addition to the electrolytes mentioned above, serum sodium, total protein, blood sugar, carbon-dioxide combining power and nonprotein nitrogen were determined on every patient, reaction, albumin-globulin fractionation and serum inorganic phosphorus determinations were made on a few patients.

In addition to the usual findings of acidosis, hyperglycemia and hemoconcentration, fluctuations in the serum potassium, magnesium and phosphorus concentrations were observed during the course of therapy. The serum potassium was above 6 milliequiv. per liter in the 5 patients on whom the determination was made on admission, the highest being 10.3 milliequiv. During therapy, the serum potassium was usually diminished within the first twenty-four hours and frequently fell to very low values (1.9 and 2.18 milliequiv. per liter). The potassium concentrations usually returned to normal levels within two or three days.

The serum magnesium, which was determined in 5 cases on admission, was slightly elevated in 2, normal in 2 and slightly below normal in 1. In most patients the serum magnesium fell at some time to abnormally low values, and then gradually rose. There was a rough correlation between the state of consciousness on admission and the serum magnesium concentrations.

Serum calcium concentrations were generally normal, although the total circulating calcium may have been reduced owing to the hemoconcentration.

The serum sodium concentration was either normal or somewhat low on admission, but soon after therapy was begun came into the normal range.

Inorganic phosphate determinations were made on only 2 patients, and in both the changes correlated with the serum potassium and blood sugar levels during therapy, which in all patients consisted in

varying amounts in physiologic saline solution, one sixth molar sodium lactate, 5 per cent glucose, plasma and insulin

Martin and Wertman<sup>14</sup> point out the similarity between the marked muscle weakness shown by several of the patients and that seen in familial periodic paralysis, another condition associated with low serum potassium concentration

Holler et al<sup>15</sup> have described patients who developed a similar syndrome during therapy for diabetic acidosis or coma. Therapy with potassium produced dramatic improvement

In interpreting the changes in serum potassium concentration, Martin and Wertman<sup>14</sup> mention possible changes in urinary excretion or use of the potassium in carbohydrate metabolism. Since magnesium is, like potassium, nitrogen and phosphorus, an important intracellular component, it is not surprising to find that the movement of magnesium follows that of the other three compounds. However, as the authors point out, until intracellular concentrations of these substances are known it will be difficult to interpret adequately changes in serum concentration. Atchley et al<sup>16</sup> showed that with the negative nitrogen balance that occurred in diabetic patients after the withdrawal of insulin, a negative phosphorus and potassium balance could be demonstrated as well. One might, by combining the data of Martin and Wertman with that of Atchley and his associates, assume that there is an intracellular depletion of potassium with increased serum concentration and loss in the urine during the period of insulin lack. On administration of insulin, the reverse would be true, but because of the potassium loss in the urine a body deficit exists, thus reducing the serum potassium concentration. If this interpretation is correct, the administration of potassium as therapy is called for, as the authors suggest

The warning given by the authors against the administration of potassium to diabetic patients in shock is well taken, and, in fact, one might even say that potassium should be administered only very cautiously, or not at all, until adequate urinary output has been established. Several reports of dangerously high blood potassium concentrations have been published and have been added to and reviewed by Finch, Sawyer and Flynn.<sup>17</sup> It is especially noteworthy that a flaccid paralysis resembling that seen with low serum potassium may result from potassium intoxication

Errebro-Knudsen<sup>18</sup> studied two healthy male medical students to determine the effect of intense muscular exercise on ketone-body formation. Both were trained sportsmen and trained for two months in riding on the bicycle ergometer so that they could perform work at about 1100 mkg a minute for upward of three hours and forty minutes — this is really exhausting physical work

For three days before the first experiment they lived on a mixed diet and then determinations were made. The second experiment was carried out after two days on a diet rich in fat and poor in carbohydrate. Thus, the total calories were between 3000 and 4000 for each diet. On the high-fat diet the figures were 57 gm of carbohydrate, 30 gm of protein and 398 gm of fat. The students weighed 74 kilograms and 67 kilograms, respectively. On a mixed diet the total ketone bodies during work rose very slightly, from 0 in one experiment to 2.4 mg per 100 cc. On one day the values started at 5.2 mg and fell to 3.5 mg at the end of the work period. Measurements were also made during the period following cessation of the exercise, and in each case a striking increase in ketone bodies occurred from three to twenty-three minutes after the end of the exercise. The values rose from 4.5 to 11.1 mg. per 100 cc as an example. The respiratory quotient rose during the period of actual exercise from 0.78 to 0.84 and then fell back to 0.78, but declined perceptibly to 0.70 during the fifteen to twenty minutes following the cessation of exercise. In the next twenty minutes it rose to 0.74. It seemed evident, therefore, that with the cessation of muscular exercise the fuel utilized changed from carbohydrate to fat. However, it also shows that the low respiratory quotient was due to an oxidation of lactic acid accumulated during work. This could be explained by a retention of carbon dioxide

The students who had been on a low-carbohydrate, high-fat diet started with respiratory quotients of 0.69 and 0.73. During work a rise in respiratory quotient to 0.73 in 1 and 0.77 in the other took place. The increase in blood acetone values was studied throughout the work period from 6 in one case and 12 in the other to 8 and 15 mg, respectively, with a further increase during the resting period up to 13 and 24 mg per 100 cc, respectively. The blood sugar values showed only a slight decline in all the experiments from about 80 mg to 54 mg per 100 cc in the experiments on a high-fat diet, with a much slighter decline in the experiments on a mixed diet

One of the reasons for undertaking these experiments was to determine whether or not the fatigue experienced on a high-fat diet is really due to the accumulation of ketone bodies. The change in concentration of ketone bodies was so slight at the end of the work period as to lead to the conclusions that the fatigue is not due to ketone bodies

#### HYPERGLYCEMIC ACTION OF HIGHLY PURIFIED ALKALINE PHOSPHATASE

Professor William Kerppola, of Helsinki, Finland, was kind enough to provide the following abstract of his recent work, *On the Hyperglycemic Action of Highly Purified Alkaline Phosphatase*, which is now in press

Highly purified alkaline phosphatase has been prepared from fresh cow udders. The strength of this preparation exceeds about five thousand times that of the first basic solution and contains about 35,000 active units (Alberts) in 1 cc. This amount may be capable of liberating about 20 gm. of glucose.

The preparation can be injected into animals and human beings without any local or general reaction. The blood picture remains unchanged.

When phosphatase is injected intravenously in rabbits during fasting the blood sugar increases suddenly and receives its highest value in an hour. Afterward it stays at an even height for about five hours and then decreases rather abruptly during the next two hours and comes gradually back to its initial value. No sugar was observed in the urine — not even when the blood sugar values were high. If phosphatase is injected subcutaneously in rabbits the blood sugar value remains unchanged but increases suddenly after seven to nine hours. The blood sugar value falls rather quickly and returns to the initial level in four to six hours. If a phosphatase is injected continuously once a day the blood sugar remains elevated as long as the treatment is continued.

If a glucose-tolerance test is made on rabbits during the phosphatase treatment, and if the curve obtained is compared with a corresponding one obtained without this treatment, a substantially raised and prolonged curve may be noted in most of the phosphatase-treated animals.

The decrease of the blood sugar value in rabbits produced by insulin injections is, under the influence of phosphatase, distinctly smaller than that in non-treated animals.

The glycogen values in the liver and the muscles of the treated animals do not differ from those of the nontreated animals.

The action of alkaline phosphatase on blood sugar seems to be quite the opposite of that of insulin.

#### CONVULSIVE STATES IN DIABETES

Convulsive states in diabetes are frequently encountered. The differential diagnosis is often difficult because in younger patients epilepsy is not uncommon. It was observed in 50 cases at the George F. Baker Clinic among children, and these were proved with abnormal electroencephalograms. The following opinion was expressed by Dr. Priscilla White<sup>11</sup>:

Hyper and hypoglycemia have been suspected as causes. It is possible that hypoglycemia merely reveals the latent case. A few cases have had serious progression. More have apparently subsided with sedation therapy which has been followed with improvement in electroencephalographic tracings. Of some interest is Case 15322 whose similar twin does not have diabetes. The electroencephalograms reveal similar deviations from the normal. The diabetic has epileptiform attacks in the absence of hypoglycemia. The non-diabetic twin has had none.

In a preceding edition from the same clinic Dr. Howard F. Root<sup>12</sup> reported the autopsy findings in 2 cases.

Case 7089 developed diabetes in March, 1920 at the age of two years and three months. Feeble-mindedness and epilepsy were evident at the age of eight years and she died in a convulsion at the age of twenty years. The histological diagnosis after examination of the brain was retarded development of the cortex, cerebellar degeneration (granular layer) and degeneration of the islands of Langerhans. For a detailed account of this patient see Case 2 in the paper of Ross and Dickerson. Case 11499 developed diabetes at the age of 43 years and epilepsy at 48 years. He died of bronchopneumonia caused by aspiration of food during a convulsion. In these 2 cases the marked mental deterioration during life and the extensive pathological changes found in the brain at autopsy suggested some congenital cause or at least damage to the brain produced by some other cause than hypoglycemia.

Ellenberg and Pollack<sup>13</sup> have discussed the problem with detailed reports of 2 cases and with the results of pathological examination in 1. Each patient had uncontrolled diabetes and showed repeated hospital admissions for ketosis or insulin reactions, and in the fatal case detailed study of the brain was made, resulting in the diagnosis of degenerative encephalopathy of unquestionably toxic origin.

Sections of the frontal lobe, stained with hematoxylin-eosin disclosed several arachnoid cell clusters in the leptomeninges. The nerve cells of the cortex presented a diversity of degenerative changes. Some were markedly swollen many however, were shrunken and contained pyknotic nuclei while some contained finely granular, deeply staining oval nuclei with an occasional enlarged nucleolus. There were other cells in which it was difficult to distinguish nucleus from cytoplasm. The outline of some cells was irregular and occasionally the cytoplasm was poorly defined. Satellitosis was increased. With Nissl stains marked central chromatolysis was seen in some areas. The Nissl substance itself was usually finely granular diffusely scattered through the cytoplasm or concentrated at the periphery at the base of the cell. Some cells stained very faintly. Both cortex and subcortex showed marked and diffuse gliosis. The blood vessels were engorged. Similar though less marked changes in the nerve cells were seen in the tegmentum pons and medulla.

In the second case dilantin, phenobarbital and tridione were each tried in full therapeutic dosage, with no measurable beneficial effect on the frequency or severity of the attacks.

An electroencephalogram made in April, 1947 again showed alpha waves with frequencies as low as 7.5 per cent with rare bursts of 6 per second activity and some single 3 per second waves. Hyperventilation did not increase the amount of slow activity. A record taken 10 minutes after the intravenous injection of 50 cc. of 50 per cent glucose showed the same characteristics.

In their discussion the authors suggest several possibilities the convulsive seizures are the manifestations of irreversible cerebral changes following repeated attacks of insulin hypoglycemia, the changes are independent of the diabetes and are actually an influence in the causation of repeated shocks, the attacks are evidence of coincidental epilepsy. They cite the possibility suggested by Greenblatt, Murray and Root that the cerebral changes are independent of the diabetes and insulin hypoglycemia and actually instigate the frequent reactions, because abnormal electroencephalograms

were encountered in 51 per cent of the problem patients with diabetes. The frequency of actual epilepsy in patients with diabetes provides a most complicating factor, and all peculiar insulin reactions should be studied with this possibility in mind.

#### ELECTROCARDIOGRAPHIC CHANGES

Changes in the electrocardiogram in diabetic acidosis have been described consisting of depression of the ST segment, lengthening of the QT interval and alternation in the T waves. The reversibility of these changes in a short period has suggested that changes in the electrolyte gallop were important factors in causing abnormalities. Martin and Wertman<sup>22</sup> studied 12 patients who entered the hospital in severe acidosis with the carbon dioxide combining power of the blood under 9 milliequiv per liter. Chemical determinations in all cases included serum calcium, potassium, sodium and magnesium levels, total plasma protein, blood sugar and carbon dioxide combining power. Sagging of the ST segment was a prominent feature when acidosis was marked, but it usually disappeared within twenty-four hours. In 19 cases of such depression of the ST segment the reaction or the blood carbon dioxide was low in 16. There was no correlation in this series between these changes and the serum potassium level. Thirty-seven records showed prolonged QT intervals, many of these occurring one to four days after intensive therapy had been started. Sixteen of these were associated with low total or ionized serum calcium or potassium, but in 21 records, that is, 57 per cent of the patients whose records showed prolonged QT intervals at normal levels of serum calcium, a high degree of correlation between low T waves and low serum potassium levels was observed. In explanation of these changes the authors point to the various factors that may be present: the relation between extracellular and intracellular electrolytes, cardiac nutrition as affected by low insulin levels and the effects of anoxia and nitrogen retention. Actually the reaction values were as low as pH 7.28, 7.05 and 7.12 in 5 cases studied, but the remainder of the series did not have a determination of the reaction. Low levels of serum potassium included one of 1.9 and others as low as 2.18 and 3.2 milliequiv per liter. In 11 cases with potassium levels under 4.2 milliequiv per liter 9 showed low or isoelectric T waves. It is well known that with high potassium levels in the blood serum high T waves may occur. With higher levels of serum potassium, depression of the ST segment will occur, and actual intraventricular block occurs at the level of 10 milliequiv and final cardiac arrest at 14 to 15 milliequiv per liter.

The study emphasizes, however, the temporary character of these changes when adequate treatment for diabetic coma is given.

#### ARTERIOSCLEROSIS

In 1928 Joslin<sup>23</sup> wrote as follows:

The diabetic lives and dies in the arteriosclerotic zone. Lives in it because two-thirds of the 4592 true diabetics in the present series originated after 39 years of age, dies in it because although the average age at death of 339 cases in the Naunyn Period was 44.8 years, the average age at death of the 607 fatal cases in the present Banting Epoch is 54.2 years, and for the last year's 60 fatal cases was 59 years. During 1925 of all the diabetics who died in Massachusetts 86 per cent were above the age of 50 years. This is the year of age in which diabetes develops most frequently for men, the most common quinquennium for both sexes being between 49 and 53 years.

Today diabetic coma having dropped to 3.1 per cent as a cause of death, the duration of the disease having increased from 4.9 to 14.1 years, and the average age at death of the diabetic cases having risen to 64.5 years, it is not surprising that cardiovascular disease causes 66.6 per cent of diabetic fatalities. A generation ago diabetic patients did not live long enough to contract hardening of the arteries.

Despite the mounting incidence of arteriosclerosis in diabetes, our group is decidedly not pessimistic. Over a generation ago, when diabetic coma claimed 63.8 per cent of our cases, we acknowledge that we felt it represented the culmination of the disease and was the act of God, but we learned our mistake five years before insulin was discovered. Today we do not believe that arteriosclerosis represents the end of the diabetic patient either in consequence of the disease or as a coincident complication. We are firmly convinced that on the whole our patients who know the most, have followed treatment most assiduously and have received from our hands what we consider our best methods of treatment not only have done the best but also show the least number of arteriosclerotic lesions. We may not have more than 8 per cent of children, as studied by Dr. Priscilla White and later reported in this review, who are free of the disease after twenty years, but we do have a few cases of severe diabetes at the very onset in children who remain free from arteriosclerotic lesions after twenty-five years of diabetes. The recovery from impending coma by Nathaniel Potter, founder of the Sansum Clinic, in 1917 led the way to other recoveries from diabetic acidosis, and we are confident, as time goes on, that the medal, which the Diabetic Fund has created for patients with diabetes of twenty-five years' duration without evidence of degenerative disease in eyes, vessels and kidneys, will eventually be granted to many patients throughout the world. Today, the question is not so much the appalling incidence of arteriosclerosis in diabetes of long standing but what patients and doctors are going to do about it.

Substantiation of the studies of Root, Bland, Gordon and White<sup>24</sup> in their comparison of the

incidence of coronary disease and angina pectoris in nondiabetic and diabetic persons has been furnished by Stearns, Schlesinger and Rudy,<sup>28</sup> whose conclusions are as follows

Functionally significant coronary artery disease was disclosed in approximately three fourths of the hearts of 50 diabetic patients by means of postmortem injection plus dissection technic. One third of these patients had died of acute coronary heart disease. One quarter of the entire group had had angina pectoris. Among diabetic women over the age of 40 the incidence of significant coronary arteriosclerosis of angina pectoris and of death due to coronary artery disease is as great as among diabetic men. This is in sharp distinction to the sex difference in these respects in the non-diabetic population. Angina pectoris,

— by establishing criteria. As indexes of control, coma, hyperglycemia, hypercholesterolemia and hepatomegaly were utilized. The results are shown in Table 7. Thus, the frequency of coma was only 17 per cent in the patients little affected with arteriosclerosis, 38 per cent in those moderately affected and in 70 per cent of those who were incapacitated. The following are the conclusions of the article

Whereas 8 per cent of 200 survivors were free from vascular lesions 92 per cent had them.

These statistics are the worst possible because they did not have modern diabetic therapy for 50 per cent of their

TABLE 7

TYPE OF PATIENT	NO. OF CASES	PATIENTS WITH COMA PERCENTAGE	HYPERGLYCEMIA* PERCENTAGE	HYPERCHOLESTEROLEMIA† PERCENTAGE	HEPATOMEGALY PERCENTAGE

Moderately affected by vascular disease	114	38	50	54	22
Incapacitated by vascular disease	50	74	54	47	36

\*Blood sugar of 40 mg. per 100 cc.

†Blood cholesterol of 250 mg. per 100 cc.

deaths due to acute coronary disease and congestive heart failure all are more common when hypertension is present in diabetic patients than when the blood pressure is normal. The severity of the coronary arteriosclerosis is correlated with the duration but not with the severity of the diabetes. Early detection of the symptoms of coronary artery disease in persons with diabetes is necessary if the sequelae of coronary arteriosclerosis are to be postponed or avoided. Mild hyperglycemia is preferable to a regimen which may result in insulin hypoglycemia and the attendant risk of precipitating myocardial infarction.

The relation of vascular disease to diabetes in childhood has been investigated by White.<sup>29</sup> Of 350 patients whose onset of diabetes occurred under fifteen years of age and who had survived twenty years or more of diabetes, 200 were examined in detail after they had had diabetes for twenty years or were known to have had arteriosclerotic lesions prior to the twentieth year of the disease. These patients are actually young adults. One hundred and ninety, or 95 per cent, are between the ages of twenty and thirty-nine years, and 10, or 5 per cent, were over forty. The sex distribution was even. Eight per cent of the patients were Jewish. The peak of age of onset was younger by seven years than it is in our entire juvenile series — namely, five years of age, compared with twelve years in all patients.

The total incidence of a vascular disease was demonstrated in 184 cases or 92 per cent. The lesions were as follows: cerebrovascular disease, 2.5 per cent, coronary insufficiency, 8 per cent, hypertension, 40 per cent, nephritis, 50 per cent, calcified arteries, 75 per cent, retinal hemorrhages, 80 per cent, and retinal sclerosis, 85 per cent.

One must refer to the original article for details, but in the course of this review Dr. White made a very definite contribution to an estimate of the control of diabetes — as contrasted to lack of control

diabetic lives. And unfortunately, comparison of patients treated with modern methods cannot be made until 1950 for it requires 15 years of diabetes for vascular lesions to become manifest to the clinician. Protamine zinc insulin was introduced into this country in 1935.

Poor control of diabetes paralleled the severity and frequency of the lesion.

Particularly notable in this study was the demonstration that pelvic arteriosclerosis was common and especially that it was of prognostic import for the fetus in pregnant patients with diabetes. Dr. Joseph H. Marks, roentgenologist at the New England Deaconess Hospital, permits me to state that in a study of 75 nondiabetic young women under forty years of age (a comparable age group to Dr. White's series), he found calcified pelvic arteries in only 1 case. And Dr. Marks also allows me to add that all but 1 of 19 cases of calcification of the vas deferens occurred in diabetic patients.

Dolger<sup>37</sup> studied 200 patients with diabetes of twenty-five years' duration, and among these there was not one who escaped vascular damage as shown by retinal hemorrhages and albuminuria or hypertension, or both, in varying degree.

The group investigated consisted of 16 whose age of onset of diabetes was below 10 years, 39 whose age of onset was between 10 and 20 years, 22 between 20 and 30 years, 43 between 30 and 40 years, and 80 between 40 and 50 years. Retinal hemorrhage was the predominant lesion when diligent search was made routinely, and it often preceded the appearance of albuminuria and/or hypertension. All three lesions appeared in the patients regardless of the age of onset or degree of severity of the diabetes, the need for insulin, the type of diabetic "control" or diet employed, the blood cholesterol levels, or the absence of x-ray evidence of arterial calcification.

Every diabetic would seem at present to be doomed to the inexorable development of vascular damage despite the benefit of insulin in prolonging life. At most, 25 years of freedom from arteriosclerosis can be offered even to the juvenile diabetic.

In a subsequent article Dolger<sup>28</sup> pointed out that "Careful scrutiny of the retina of each patient over the course of years indicated that the earliest clinical manifestation of vascular damage can be found in the eye." In the discussion that followed he reported that vitamins C and P, rutin and hesperidin did not influence retinal hemorrhages significantly because of spontaneous remissions and exacerbations displayed by these lesions, and he considered that work being done with cytochrome C or related oxidized enzymes was far more provocative and pertinent than vitamin research. The usefulness of determinations by capillary fragility proved, in his hands, so variable as to be valueless, being positive one day, negative in twenty-four hours and positive again a week later.

It is the impression of Dr. Priscilla White, who has followed the progress of our cases of retinitis proliferans, especially in young diabetic persons, that there has been much less rapid progress of these lesions since the introduction of rutin. Further-

since 1917, 42 are known to have died during 1946, the average age at death being 60.6 years and the duration of diabetes being 13.1 years. Coronary thrombosis was responsible for 11 deaths, carcinoma for 7, cerebral thrombosis or hemorrhage for 6, diabetic coma for 4, and congestive heart failure due to hypertension or arteriosclerosis for 3, with intercapillary glomerulosclerosis, rheumatic heart disease, pyelonephritis and uremia, traumatic fracture of the spine, gangrene of the leg, tuberculosis of the lung, Addison's disease and xanthomatosis of the liver (primary) accounting for 1 each.

Only 3 juvenile diabetic patients were known to have died. Autopsy on 2 revealed extensive intercapillary glomerulosclerosis, and the clinical picture in the third led to the same diagnosis before he left the hospital to die elsewhere a few months later.

Vascular degeneration, so evident, remains the greatest challenge to the physician treating diabetes today. It is our incentive for insisting on rigid diabetic control in our patients.

TABLE 8 Control of Diabetes with Separate Injections and with Mixtures

TYPE OF DIABETES	RESULTS	SEPARATE INJECTION	SYRINGE MIXTURE	BOTTLE MIXTURE
		%	%	%
Adult	{ Excellent	33.0	34.9	50.0
	{ Good	51.0	44.9	36.1
	{ Poor	16.0	20.2	13.9
Juvenile	{ Excellent	15.8	15.5	36.0
	{ Good	55.6	49.1	36.0
	{ Poor	28.6	35.2	28.0

more, she has not noted the wide variations of capillary fragility observed by Dr. Dolger. Dr. Howard F. Root, who especially has been concerned with the use of rutin in our entire clinic, substantiates her opinion.

At the Mason Clinic in Seattle during 1946, Palmer<sup>29</sup> reported 236 patients seen for the first time. The average age was 49.8 years, and the average age at onset 44.2 years. Among the new adult patients degenerative diseases were very common. Thus, 41 per cent had hypertensive or arteriosclerotic heart disease, whereas of 429 diabetic patients admitted to the hospital, including the 236 new cases in the outpatient department, hypertensive and arteriosclerotic heart disease was present in 61.6 per cent. There was 1 death from diabetic coma among the 13 cases of acidosis treated, and of the 13 diabetic patients who were pregnant, 8 were delivered by cesarean section between the thirty-fifth and thirty-eighth weeks, resulting in 8 living children, in the remaining 5 cases, 3 infants were delivered spontaneously, 1 was stillborn and the other 2 died during the neonatal period. There was a miscarriage at thirteen weeks and a therapeutic abortion at five months because of the presence of uremia in the mother. Of the 2813 patients with diabetes followed at the Mason Clinic

In a subsequent article Palmer<sup>30</sup> reports favorably upon the use of insulin mixtures (Table 8). It is obvious that the ideal mixture has not been discovered, and in general it seems desirable for physicians to decide on the method of treatment of their patients with protamine-zinc insulin, separate injections of regular insulin or crystalline insulin and of protamine-zinc insulin, a mixture in the syringe, or premixed in a bottle, rather than to attempt the use of all four methods, which would almost certainly result in confusion. If physicians will only be patient for a year or two, undoubtedly new methods for the use of insulin will be found.

Campos and Molina,<sup>31</sup> in Buenos Aires, observed 25 consecutive cases of diabetes at all ages and reported on the fundus oculi. All these patients were poorly treated over a long period, and the most frequent combination was hypoalbuminemia, hypocholesterolemia and diabetic retinopathy. This combination appeared in 11 out of the 25 cases.

(To be concluded)

### CASE 34131

#### PRESENTATION OF CASE

A twenty-two-year-old linoleum layer was admitted to the hospital because of red urine.

Two months before admission, following a football game, he developed a sore throat accompanied by epistaxis and occasional biting of the tongue while asleep. Following this episode, which lasted an unstarred period, he returned to work but was easily fatigued and slept a great deal. Three weeks before entry he again had severe epistaxes, sore throat and malaise. He had to leave his job on several occasions because of fatigue and drowsiness. During this period he developed red urine and was sent to another hospital, where he was catheterized because of inability to void. Thirty-two ounces of urine was obtained. While there he had a generalized convulsion. One day before transfer to this hospital he was again catheterized because of continuing retention. The face, neck, and eyelids were edematous. He was treated with penicillin.

The patient had been an apparently normal child. At the age of six he developed enuresis. Repeated attempts to break him of this habit were unsuccessful. Urine was frequently analyzed but found to be normal. The enuresis persisted until two years before entry, when he married. Since then he had averted difficulty by getting up to void during the night. At the age of eight he had an appendectomy, and at ten the tonsils and adenoids were removed. At thirteen he was found to have an abdominal tumor. Examination revealed a distended bladder.

A suprapubic cystostomy was performed, and no abnormality was found. The discharge diagnosis was "Distended bladder—retention of urine." About three years before entry he was rejected from the Army because of a "spina bifida." During the past two years he was noticed to limp to an increasing degree.

Physical examination revealed a very pale man in extremis. The breath was uremic. He had generalized twitching of the arms and a positive Chvostek sign. The skin was dry, and the neck veins were prominent. Examination of the fundi was negative. There was clotted blood in the nose. The apex of the heart was at the anterior axillary line, and there was a Grade III systolic murmur heard over the whole precordium but loudest at the pulmonic area. The chest was clear except for widely heard rhonchi. There was no ankle edema. There was an abscess in the right buttock. Some atrophy of the right calf muscles was present. There was bilateral pes-cavus deformity.

The temperature was 98.6°F., the pulse 90, and the respirations 14. The blood pressure was 180 systolic, 80 diastolic.

Examination of the blood showed a red-cell count of 2,800,000, with 10 gm. of hemoglobin, and a white-cell count of 25,000, with 88 per cent neutrophils and 12 per cent lymphocytes. The blood chloride was 98, and the carbon dioxide 9.1 milliequiv per liter. The total protein was 6.8 gm. per 100 cc., and the nonprotein nitrogen 146 mg. The urine was red and had a specific gravity of 1.010. There was a +++ test for albumin and a + test for acetone. The sediment was loaded with red and white cells and there were rare casts.

One hour after admission the patient had a generalized convulsion, controlled by 15 gm. of calcium levulinate. He also received luminal, cedilant and magnesium sulfate. He slowly received 1000 cc. of 5 per cent dextrose in water intravenously. He remained in a semicomatose state. An indwelling catheter was inserted, and in one fifteen-hour period drained 1200 cc. of grossly bloody urine. The blood pressure, which had been running about 140 systolic, 70 diastolic, fell to 100 systolic, 55 diastolic, for no apparent reason, and he died thirty-six hours after admission. In the last fourteen hours of life he passed 10 cc. of urine.

## DIFFERENTIAL DIAGNOSIS

DR EARLE M CHAPMAN This is indeed an interesting case and obviously is presented for the diagnosis of the type of kidney disease that led this man to die in rather classic uremia. He was in the hospital thirty-six hours so that very few studies were done.

But the review of the past history and the known facts presented here can lead to a diagnosis of a well recognized entity. I believe that he had a congenital defect — spina bifida — which eventually caused progressive changes in the spinal cord and what might be called a cord bladder. With this he had the other evidence of spina bifida — atrophy of the calf muscles and a bilateral pes-cavus deformity. Evidently through his early life this syndrome was not recognized. We cannot tell from the record, but I doubt it, because if it had been recognized, the patient would certainly not have been subjected to a suprapubic cystotomy unless a congenital valvular deformity, either in the neck of the bladder or in the urethra, was being sought. That this was not an acute process such as acute glomerulonephritis or acute pyelonephritis is indicated by the fact that he had evidence of chronic renal disease. In other words, the heart was enlarged, and he had hypertension, anemia and a fixation of the specific gravity of the urine at 1.010. All these findings indicate the long duration of the disease.

There is one note in the record that I take exception to — that after admission to the hospital an indwelling catheter was inserted and in one fifteen-minute period 1200 cc. of grossly bloody urine was drained, the blood pressure, which had been running about 140 systolic, 70 diastolic, fell to 100 systolic, 55 diastolic for "no apparent reason." It has been the practice of the Genitourinary Service here that patients with chronic, long-standing obstruction to urinary outflow should not be decompressed rapidly, since removal of large quantities of urine in a short time leads to shock, fall of blood pressure and perhaps anuria. I think this is an example of such a reaction in this patient.

I can add little else. This is a recognized entity, although one has difficulty in finding a clear-cut description of it in textbooks. If the urinary tract had been studied and retrograde pyelograms done, which I judge were not since they have not been mentioned, the examinations would have shown a chronic atonic bladder, hydroureter and hydronephrosis. In this condition the kidneys end up with thin shells of cortex, — usually with some pyelonephritis, — but in this case there was very little evidence of pyelonephritis.

In conclusion, I would say that this man had spina bifida, cord bladder and the other evidence of central-nervous-system damage, and that with this he had an atonic, large bladder, a hydroureter, back

pressure on the kidneys and small, atrophic kidneys, with a narrow rim of cortical tissue, and that he finally died in uremia, which at the end, at least, was not aided by the sudden withdrawal of a large amount of urine from the bladder.

DR H J KOWALSKI I should like to ask Dr Chapman how he explains the fact that the urine had been normal for a number of years. The patient's mother was a nurse and she had taken frequent specimens to a hospital for analysis and they had been consistently normal. Although we believed that this was acute nephritis, there were several features about it that were somewhat confusing. One was the low specific gravity of the urine (1.010). The fact that he had passed bloody urine and had renal failure following a sore throat, with epistaxis, of course, favored acute nephritis. Also, he had a high white-cell count. The terminal event was scanty, bloody urine, which is frequently seen in the end stage of this kind of process. I did not believe that this man died in shock. The blood pressure remained fairly well sustained, the pulse was good, and there were no signs of sweating or evidence in the extremities suggesting shock.

DR FLETCHER H COLBY I should think it was unusual even in the terminal stages of the condition such as you describe to have so much hematuria unless associated with a severe, acute infectious process or some other disease in the kidney. It is true that sudden decompression is not desirable, but the record says fifteen hours, not fifteen minutes.

DR CHAPMAN I misread the record. I shall have to retract that statement.

DR COLBY There is no adequate explanation for the copious hematuria?

DR CHAPMAN That is a puzzling point.

DR ALLAN M BUTLER One sees hematuria with pyelonephritis and pyuria.

## CLINICAL DIAGNOSES

Acute glomerulonephritis  
Uremia

## DR CHAPMAN'S DIAGNOSES

Spina bifida  
Atonic bladder  
Hydroureters  
Atrophic kidneys  
Uremia

## ANATOMICAL DIAGNOSES

*Intradural lipoma of sacral canal*  
*Spina bifida occulta*  
Dilatation and hypertrophy of bladder  
Hydroureters, bilateral  
Hydronephrosis, bilateral  
*Pyelonephritis, chronic (with uremia)*  
Parathyroid hyperplasia, secondary

## PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN Autopsy showed what Dr Chapman predicted. The bladder was tremendous, very thick and markedly trabeculated. There were numerous erosions of the mucosa. It is quite possible that the massive hematuria came from one or more of the mucosal erosions. Both ureters were markedly distended and thickened. There was a marked hydronephrosis, with only a shell of normal cortex remaining (Fig. 1). Not knowing about the spina bifida at that time, we immediately looked for a congenital valve in the urethra or some form of obstruction, but we were unable to find any. We then studied the history a bit more thoroughly and decided that the next thing to do was to

FIGURE 1. Marked Hydronephrosis and Hydronecrosis. The bladder is markedly thickened and trabeculated. (Only a portion of the bladder is in the photograph and it has been superimposed on the mid portions of the ureters.)

examine the spinal cord and the spine. Dr Kubik, will you tell us about that?

DR CHARLES S. KUBIK. There was a spina bifida occulta involving the arch of the fifth lumbar vertebra and all of the sacrum.

Filling the sacral canal was an intradural mass of fat, or lipoma, measuring 5 cm. in length and from 2 to 3 cm. in diameter. This lay posterior to the

spinal cord, which extended to the lower part of the sacral canal and was attached to the tumor by dense strands of fibrous tissue (Fig. 2). A condition such as this is not infrequently associated with spina bifida.

At birth in the normal person the lower end of the spinal cord occupies the lower part of the sacral

FIGURE 2. Posterior (A) and Anterior (B) Views of the Lower Portion of the Spinal Cord and Intradural Lipoma of the Sacral Canal in a Case of Spina Bifida Occulta.

The lowest visible spinal nerves in the posterior view (A) are the fifth lumbar. Note the upward course of these and other lumbar nerves.

canal. As growth takes place the spinal cord does not increase in length to the same extent as the vertebral column, so that in the adult the cord terminates at about the first lumbar vertebra and the vertebral canal below that is occupied by the spinal nerves of the cauda equina. In this case there was no cauda equina, the tip of the cord was anchored to the lower part of the sacral canal and held in that position as the vertebral column increased in length, with the result that the cord was stretched out and the course of the sacral and lower lumbar spinal nerves was actually reversed.

DR BUTLER. Was there any hydrocephalus?

DR KUBIK. No—and no deformity of the cervical cord or cerebellum. In some cases of spina bifida the medulla and inferior poles of the cere-

bellum may be pulled down into the foramen magnum (Arnold-Chiari deformity), but that was not so in this case

DR J B AYER It would be interesting to know whether the patient had other deformities I suppose he was too sick to find out

DR KUBIK He had clubfeet

DR AYER Was he paralyzed?

DR KUBIK No, but there was some atrophy and the patient had a limp

DR AYER That is consistent with other tumors of this character, with nerves running through the tumor without paralysis

DR KUBIK Signs of pyramidal-tract disease sometimes develop at about the age of puberty, presumably because the cord is stretched as a result of active growth at that time

DR CASTLEMAN Further evidence of long-standing renal impairment was the increased size of the parathyroid glands They weighed over 400 mg (about three times the normal weight) and microscopically showed secondary hyperplasia

DR CHAPMAN What did you find in the kidneys?

DR CASTLEMAN An extensive, chronic, inflammatory process — pyelonephritis, such as one would expect, with a great deal of fibrosis and not much cellular infiltration, which may account for the absence of pyuria

DR KOWALSKI Do you mean that the blood may have come from the bladder? The patient had hematuria three or four days before he entered the hospital

DR CASTLEMAN I still believe it came from the bladder There were no erosions in the ureter or pelves, but there were in the bladder

### CASE 34132

#### PRESENTATION OF CASE

An eight-week-old female infant was admitted to the hospital with a history of jaundice for two weeks and clay-colored stools for one week

The child had been born three weeks prematurely following an uneventful pregnancy Delivery was normal The birth weight was 6 pounds, 12 ounces, and she had gained steadily until the day before admission to 10 pounds, 8 ounces The patient's mother stated that jaundice was noticed for the first time two weeks before admission and then increased progressively One week before admission the stools became clay colored instead of the usual yellow color, but there was no change in bowel frequency or stool consistence During the night before admission the patient became irritable but continued to feed On the morning of entry she vomited orange juice and ceased taking fluids, and the stools became loose, green, and frequent (twenty during the day) The urine was orange colored for the first time In the eight hours previous to entry the

patient had stiffness of the extremities accompanied by frothing at the mouth There had been no cough, hematemesis, melena, bruising or head trauma

Two siblings, five and two and a half years old, were well and had never had jaundice or convulsions

Physical examination revealed an acutely ill, pallid, jaundiced child actively convulsing, with tonic upper extremities and clonic movements of the left leg Anisocoria was present, the right pupil being larger than the left The anterior fontanelle was tense The liver edge was palpated four fingerbreadths below the right costal margin, and the spleen three fingerbreadths below the left costal margin The abdomen felt full, and an umbilical hernia was present There was no purpura, but the tourniquet test was positive

The temperature was 99°F, the pulse 140, and the respirations 45

Examination of the blood revealed a white-cell count of 20,000, with 46 per cent neutrophils, 33 per cent large lymphocytes, 9 per cent monocytes and 12 per cent blast forms The hemoglobin was 8.5 gm The urine was negative for urobilinogen and gave a + test for urobilin A Harrison spot test was positive A digital specimen of stool gave a ++ guaiac reaction The bleeding time was 3½ minutes and the clotting time, 2 or 3 minutes The prothrombin time (after vitamin K therapy for twelve hours) was 13 seconds (normal, 16 seconds) The blood was Group O and Rh— A van den Bergh reaction was 6.4 mg per 100 cc indirect and 1.8 mg direct The total protein was 6.4 gm per 100 cc Lumbar puncture showed an initial spinal-fluid pressure equivalent to 290 mm of water, after removal of 4 cc the pressure was equivalent to 110 mm of water The fluid was orange colored, with 20,000 red cells, 500 white cells per cubic millimeter and a +++ Pandy test. The total protein was 10.40 gm per 100 cc, and the sugar 165 mg per 100 cc A subdural tap on the left was negative, on the right 7 cc of grossly bloody fluid under considerable pressure was removed and clotted on standing An x-ray film of the chest was normal A film of the abdomen showed a liver that appeared to be enlarged The splenic outline was not definitely traced The enlargement of the liver appeared to involve the left lobe

The patient remained in coma, with many convulsive episodes There was no remarkable response to repeated subdural taps or lumbar punctures She was given blood transfusion, vitamin K and parenteral feedings She expired at the end of the second hospital day after a few hours of hyperpyrexia

#### DIFFERENTIAL DIAGNOSIS

DR LEO B BURGIN In summary this eight-week-old infant had a disturbance involving two systems, the central nervous system and the biliary system

I propose to deal with these separately and then, if possible, to relate them.

The conditions commonly causing jaundice during the early weeks of life are icterus neonatorum, congenital syphilis, erythroblastosis fetalis, sepsis and congenital malformations of the bile ducts—that is, atresia.

The history of increasing jaundice, clay-colored stools and orange-colored urine suggests a regurgitation or obstructive jaundice. Bile was found in the urine. Urobilinogen was absent.

Icterus neonatorum is generally considered to be a hemolytic or retention type of jaundice. It occurs in the first week of life. It would hardly be expected to continue as long as eight weeks, nor would its appearance be delayed until six weeks.

Syphilis does not seem likely. The family history was negative. There was no history of sniffles, rash or marked anemia, with or without an erythroblastic picture. Moreover, this baby thrived exceedingly well up to the time of admission. The hepatosplenomegaly and jaundice are consistent, but that is all.

Against erythroblastosis is the fact that the patient was Rh—. The jaundice appeared six weeks after delivery, and there were not the profound anemia and excessive numbers of erythroblasts usually found in the blood smear.

Sepsis with hemolysis might produce this picture. There is, however, no report of fever, although it is possible for infants to have overwhelming sepsis without fever. The elevated white-cell count may have been partially due to dehydration. There does not appear to have been a primary focus for infection unless we consider the diarrhea, which occurred terminally, however, some two weeks after the onset of the jaundice. Finally, the jaundice for the most part was obstructive although there is some evidence of a retention jaundice in the elevated indirect van den Bergh reaction. All in all, the course and history are against sepsis.

We come then to congenital atresia of the bile ducts. In this disorder, jaundice does not appear immediately. There is apt to be a period of two or three weeks before it is noted. In this case, however, jaundice did not appear until the child was six weeks old. It is possible that a slight degree of jaundice went unnoticed for a week or two earlier. Usually clay-colored stools are present from birth, but they may be tinged slightly with bile-stained mucous cells from time to time. Generally, these infants thrive quite well despite the absence of bile for digestion. Certainly, this child did quite well nutritionally almost to the day of death. In considering this diagnosis, I am disturbed by the high level of the indirect van den Bergh reaction. I can only explain it by suggesting that with increasing biliary obstruction the liver cells became functionally damaged and consequently unable to handle the normal daily destruction of red cells.

One other condition that I should like to mention is biliary obstruction from inspissated bile. The only difference from atresia is intermittency of the jaundice. We might infer this from the lack of history of clay-colored stools at the onset.

As for the central-nervous-system disturbance, the evidence presented points to subarachnoid hemorrhage as well as subdural hemorrhage. The presence of fresh red cells, increased protein in the lumbar tap and the history and findings of active convulsions suggest that this bleeding was recent. The most common cause of such bleeding is trauma, of which there was no history. It is possible that this bleeding might have occurred as a result of convulsions primarily due to the subdural hematoma, which was proved by tap.

Subdural hematomas are not uncommon in infancy. Trauma, not necessarily obvious at the time of delivery, may be responsible. The symptoms of increased pressure arise as the red cells in the hematoma disintegrate and hemoglobin and protein pass into the serum, producing a hypertonic fluid with subsequent increase in the size of the mass. The blood obtained from the tap clotted on standing. This suggests recent bleeding. Other causes for both sources of bleeding at this age are scurvy and hemorrhagic tendencies. There was no history of vitamin C intake, and I doubt whether eight weeks is sufficient to produce scorbutic symptoms. There was nothing in the blood picture to suggest purpura, leukemia or other blood dyscrasias. The prothrombin time was normal, but this was after vitamin K administration. We know that the patient had obstructive jaundice. With this disorder bleeding tendencies are not uncommon, and I believe that the subdural and subarachnoid hemorrhages were due to vitamin K deficiency secondary to obstructive jaundice.

Despite the delay in onset of jaundice and in the appearance of clay-colored stools, I believe this infant was suffering from congenital atresia of the bile ducts, subdural hematoma and subarachnoid hemorrhage secondary to liver damage.

There were some x-ray films that I should like to see.

DR STANLEY M. WYMAN: The liver seems a little large. The spleen cannot be traced accurately. I am not too impressed by the abnormal contour of the liver. The lung fields are clear, and the heart is not remarkable.

DR BURGIN: I supposed, when I read about the enlargement of the left lobe of the liver, that possibly one hepatic duct closed later than the other hepatic duct, which might account for the greater enlargement on one side of the liver than the other. But I am not sure that that is a good explanation.

DR ALLAN M. BUTLER: I think the history as given omits the fact that a blood culture was taken and found to be negative.

cine was supplied to the stricken country, in addition to 32 tons of medical supplies and equipment

The various activities of this organization make up a considerable list. The technical health assistance that had been given to fourteen devastated countries by UNRRA was assumed by WHO. Two hundred and twelve fellowships in public health were awarded to representatives of various governments for study outside their own countries. The WHO mission in China assumed emergency public-health work as well as the training of medical and technical personnel, in Greece a malaria-control problem that included the spraying or dusting with DDT of nearly 3500 malaria-ridden communities was inaugurated.

Ethiopia, whose technical experts were liquidated during the war with Italy, was assisted in developing basic programs of medical training and public-health administration, the Ethiopian Red Cross was revived and reorganized.

In addition a number of studies were made by committees of experts. The Committee for the Preparation of the Sixth Decennial Revision of the International Lists of Diseases and Causes of Death made improvements in the classification of vital statistics. The Expert Committee on Biological Standardization adopted international standards for vitamin E, heparin and penicillin, and other expert committees considered such subjects as malaria, tuberculosis and venereal disease, the unification of pharmacopeias, pilgrimages (such as the Mecca pilgrimage), quarantine, yellow fever, habit-forming drugs, and alcoholism.

Under the joint auspices of the Interim Commission and the Unitarian Service Committee a group of eight American and two Swiss physicians and surgeons visited Austria last summer on a teaching mission.

The World Health Organization will become a specialized agency of the United Nations when twenty-six States members of the UN have ratified its constitution. This has already been done by eighteen members. Within six months of final ratification the first World Health Assembly will convene, and the permanent machinery of the organization will be established.

## NOW I LAY ME —

THOSE who received their medical training in a previous decade and have not since engaged in the practice of modern surgery may find themselves a little aghast at encountering postoperative patients walking about their rooms still reeking of ether. It is, however, in the tradition of today. We know that it is all for the best and that by these modern methods thromboses are prevented and embolic disturbances avoided. We have been made aware of the fact that despite their sojourn in a world of violence, most people still die in bed.

Those who indulge in a more placid form of medical practice than surgery have also become aware of the risks entailed in permitting patients to take too solidly to their beds. Levine<sup>1</sup> called attention to a few of them as long ago as September, 1944, when he showed that with bed rest a shift of edema may occur from the dependent parts of the anatomy to the patient's back, that recumbency increases the total blood volume, and adds the risk of hypostatic pneumonia, that in old men urinary retention may develop after recumbency has been instituted. In other words, there are dangers attendant upon bed rest besides that of pulmonary embolism.

Too often the colloquial expression "he took to his bed" implies a grim finality — a failure to rise again from the horizontal position.

Asher<sup>2</sup> carries the point still farther, expressing our old, innocent, somewhat naïve attitude toward bed in a quotation from *Hymns Ancient and Modern*, No. 23, Verse 3, as follows:

Teach me to live that I may dread  
The grave as little as my bed

Perhaps this obsolete attitude toward recumbency was also represented by the famous bed of Ware, on which several scores of couples could lie in apparent comfort. Disraeli, we are told, when in doubt took to his bed — a plagiarism on Voltaire.

Dr. Asher lists the strain of an overaddiction to recumbency on the respiratory system, the blood vessels, the skin, the muscles and joints, the bones, the renal tract, the alimentary tract, the nervous system and the mind.

Look at a patient lying long in bed. What a pathetic picture he makes! The blood clotting in his veins, the lime draining from his bones, the scybala stacking up in his colon, the flesh rotting from his seat, the urine leaking from his distended bladder, and the spirit evaporating from his soul.

The picture is overdrawn, he admits. Bed has its uses even in sickness, although the cardiac patient is often better off in a chair and all patients need exercise as soon as they are able to take it. It is moderation that Dr. Asher urges and that he implies in his final poetic outburst:

Teach us to live that we may dread  
Unnecessary time in bed  
Get people up and we may save  
Our patients from an early grave.

## MASSACHUSETTS MEDICAL SOCIETY

### TREASURER'S REPORT COVERING REFUND DISTRIBUTION

The Treasurer of the Massachusetts Medical Society makes the following report regarding the refund to district societies for 1948:

The Council voted to distribute the sum of \$8000.00 to district societies. The total number of payments of annual dues received by the Treasurer by March 1 to be counted for the refund, was 4541. Therefore the refund to the district societies for each paid fellow is \$1.76.

The following table gives the number of payments as of March 1, and the refund to each district as of March 12:

DISTRICT	NUMBER REPORTED PAID	REFUND
Barnstable	39	\$68.65
Berkshire	122	214.72
Bristol North	58	102.68
Bristol South	183	322.84
Essex North	180	317.01
Essex South	252	444.02
Franklin	40	70.40
Hampden	287	505.68
Hampshire	61	107.36
Middlesex East	137	241.38
Middlesex North	125	220.36
Middlesex South	937	1,650.06
Norfolk	828	1,459.02
Norfolk South	148	260.69
Plymouth	135	238.03
Suffolk	549	967.01
Worcester	374	658.69
Worcester North	86	151.40
	4,541	\$8,000.00

In 1947 for comparison the total number of payments for the refund was 4527.

ELIOT HUBBARD, JR., M.D. Treasurer

### COMMENT

Chicken pox, diphtheria, bacillary dysentery, measles, mumps, poliomyelitis and undulant fever are above the seven year median for these diseases.

German measles, lobar pneumonia, scarlet fever and whooping cough are below the seven year median.

Chicken pox is at the third highest prevalence for the month; the total cases having exceeded only in 1944 and 1947.

Mumps is epidemic in Greater Metropolitan Boston and the northeastern part of the State as far as the New Hampshire line.

For the second consecutive month scarlet fever is at low level since 1906.

Whooping cough is at the lowest prevalence since 1917.

### GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Diphtheria was reported from Belmont, Cambridge, 1; Everett 1; Revere 4; Somerville 2; Wayland 1; Winchester 3; total 20.

Dysentery bacillary was reported from 1 total 11.

Encephalitis infectiosa was reported from 1 total 1.

Malaria was reported from Malden, 1; total 3.

Meningitis meningococcal was reported from Fall River 1; Lexington 4; Malden, 1; total 6.

Meningitis Pfeiffer-bacillus was reported from 1 total 1.

Meningitis pneumococcal was reported from Weston 1 total 2.

Meningitis other forms was reported from Quincy 1 total 2.

Meningitis, undetermined, was reported from 1 North Attleboro 1; total 2.

Poliomyelitis was reported from 1 total 2.

Salmonellosis was reported from Malden 1; Melrose 1; total 2.

Septic sore throat was reported from 1 Falmouth 1; total 2.

Typhoid fever was reported from 1 total 1.

Undulant fever was reported from 1 Gloucester 1; total 1.

## CORRESPONDENCE

### BLOOD GROUPING FACILITIES IN JEOPARDY

*To the Editor* The following letter from Commissioner Vlado A. Getting discloses a situation that is distressing to many of us who appreciate the importance of the laboratory services offered by the Massachusetts Department of Public Health. It will be even more distressing when physicians and patients throughout the Commonwealth realize that this important assistance can no longer be obtained.

When the Executive Committee of the Blood Grouping Laboratory appropriated the money, two years in succession, to enable the state laboratory to perform Rh testing and blood grouping on blood samples submitted by physicians, particularly in prenatal cases, it was our desire to explore the usefulness of such testing as a public-health measure and to find out how many doctors would avail themselves of this free testing for the benefit of their patients. Scientifically, there can be no question that Rh typing and blood grouping are important, not only to the general public but more particularly to women during gestation. By knowing the blood group and Rh type, the physician can protect his patient against the hazards of emergency need for transfusion, which occurs suddenly as a complication of pregnancy from time to time, and can protect the infant, in certain cases, by helping establish promptly the diagnosis of erythroblastosis fetalis in the newborn and by providing immediate treatment. That this service by the state laboratory has been most useful is proved by the large number of doctors who have availed themselves of it, and by the fact that more than 1000 cases per month are now being tested. Certainly the peak has not been reached, and eventually it is quite possible that five or six times the present number of specimens would be sent to the State Laboratory if this work were permitted to continue. Unfortunately, the Blood Grouping Laboratory cannot continue to support from its research funds what is essentially a routine procedure, no matter how important this is as a public-health measure. It seems a pity, therefore, that this work should be allowed to lapse merely because its great value is not recognized by a committee of laymen.

I trust that this correspondence will help bring a distressing situation to the attention of physicians of the Commonwealth who recognize the need for this protective laboratory work, and that these physicians and their patients who have benefited will call the attention of their legislators to the error that will be made if the services of the state laboratory are curtailed in this respect.

Dr. Louis K. Diamond  
Blood Grouping Laboratory  
Children's Hospital  
300 Longwood Avenue  
Boston, Massachusetts

Dear Dr. Diamond:

I am writing to inquire about the possibility of the continuation of a grant from your organization to provide Rh typing and blood grouping of bloods from pregnant women.

As you know, last year and this, the Department requested funds to carry on this service in its budget. The funds were not provided for the current year, and the item was not included in the Governor's budget, which was presented to the Legislature in January.

I had an opportunity to present this matter once more to the Ways and Means Committee a few days ago. I shall not know until the budget is passed whether further consideration will be given to this request, but because of the extraordinary demands being made upon the Legislature this year, it is altogether likely that the funds needed for this work will not be provided.

As you know, we were able to carry out over 9000 tests on pregnant women for physicians of the Commonwealth during the last twelve months. It will be quite a blow to the Department if it becomes necessary to curtail this service.

We are in essentially the same situation in diagnostic tests for virus diseases, which have been carried out in co-operation with the Virus Laboratory of the Harvard Medical School. Sufficient funds for the continuation of this work were not included in the expense item of the Division of Communicable Diseases in the budget submitted to the Legislature.

May I please hear from you regarding the possibility of continuing this service under a grant from your organization?

VLADO A. GETTING  
Commissioner

Commonwealth of Massachusetts  
Department of Public Health  
State House  
Boston

Boston

### FURTHER COMMENT ON "UNNECESSARY OPERATIONS"

*To the Editor* I wish to subscribe to the comments made in the editorial "Unnecessary Operations," which appeared in the March 4 issue of the *Journal*. I imagine this editorial was written by one of your associates who is extremely well versed and qualified to comment on this subject. I simply wish to agree with statements and to add a comment or two based on my own experience.

The statistical improvement in mortality rates from appendicitis is most gratifying to everyone. The reasons for this improvement are, in my opinion, the result of better management of the individual patient and to a lesser extent better operative technique, and antibiotics and chemotherapy. It is not attributable to earlier or more accurate diagnoses so far as my observations indicate. Admissions to a specialized hospital for the young seem very much the same as they did fifteen years ago so far as appendiceal peritonitis is concerned. There has been an opportunity to observe admissions to two suburban and one Government hospital where the same situation obtains. My own experience in the past two years is similar.

I believe, therefore, that the article that inspired the editorial is capable of doing a great deal of harm. Relatively speaking, appendicitis is not a rare disease in childhood.

Prompt recognition of the disease is not common. Appendicitis is a diagnosis to be considered seriously when abdominal pain is a presenting symptom, and presence of localized tenderness, with or without supporting findings, is of the greatest importance. Home observation of such

patients is often unsatisfactory owing to environmental conditions including the emotional status of the family. Frequently, observations and laboratory support may not be feasible in the home. The proper place for a patient with an abdominal pain and without a definite diagnosis is in a hospital that is properly equipped and staffed.

HENRY W. HILDON, JR. M.D.

1101 Beacon Street  
Brookline

### NO MORE SPECIALISTS NEEDED

To the Editor: In the editorial entitled "The Second Age of Dependency" which appeared in the March 4 issue of the *Journal*, the last paragraph reads: "Perhaps we may need to add yet another specialty that will determine degrees of health rather than of disease whose representatives will endeavor to preserve, extend and enhance the physical and mental well being of the healthy and labor to keep apart the fields of the pediatrician and the geriatricist."

This sentence brings up a rather important point which needs certain clarification. The point is that a new, separate field of specialization may be needed. The clarification is that such a field properly should exist so far as the research aspect is concerned but it should not exist so far as the aspects of teaching or clinical practice are concerned. This is neither an argument simply of the old familiar general practitioner vs. specialist variety nor is it one of semantics.

The opinion of the slowly growing but still small number of physicians who have been interested in this field for many years (of whom I happen to be one) is somewhat as follows. The fundamental approach to a student's study of medicine should be through a study of man as a whole not through unrelated study of his various anatomic, physiologic and psychologic parts. Secondly the anthropologic, sociologic and general environmental aspects of man's existence should be given more consideration in the teaching given by medical school staffs. Thirdly the concept that an adequate understanding of man can be obtained through a consideration only of his symptoms or his disease is basically fallacious and should be replaced by a primary approach to man through consideration of him in his healthy state; the secondary approach being through disease. Finally these suggested changes in the fundamental approach to the study of medicine should become inherent in the approach of all teachers whatever specialty they may represent and should not become the province of a newly created group of specialists.

JOHN P. MORRIS, M.D.

Harvard University  
Department of Hygiene

### BOOKS RECEIVED

The receipt of the following books is acknowledged and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*Studies from the Rockefeller Institute for Medical Research*. Reprints. Volume 133. 8<sup>o</sup> paper. 604 pp. New York: The Rockefeller Institute for Medical Research. 1947. \$2.00.

This volume is made up of reprints of papers originally printed in various periodicals and here brought together for convenience in reference. They constitute the results of investigations conducted at the Rockefeller Institute and published in 1946.

*A Handbook of Ocular Therapeutics*. By the late Sanford R. Gifford, M.D., professor of ophthalmology, Northwestern University Medical School, Chicago. Revised by Derreck Vail, M.D., D.O. (Oxon), professor of ophthalmology, Northwestern University Medical School, Chicago. Fourth edition. 8<sup>o</sup> cloth, 336 pp. with 66 illustrations. Philadelphia: Lea and Febiger. 1947. \$5.00.

Dr. Gifford died in 1944 and Dr. Vail assumed the task of revising this fourth edition of a standard textbook. There has been some revision to bring the text up to date. New material has been added on penicillin and the sulfonamides. The chapter on disorders of the muscular apparatus has been

eliminated since it was considered out of place in a book of this type. Selected references are appended to each chapter and there is a good index. The book is well published in every way. Although it has passed through four editions there is nothing to indicate its publication history. This is to be deplored for a book worthy of repeated editions should at least give the dates of the various editions on the back of the title page. The work is recommended for all medical libraries and should prove of value to specialists in the field of ophthalmology.

*Internal Medicine in General Practice*. By Robert P. McCombs, M.D., assistant professor of medicine and director of postgraduate teaching, Tufts College Medical School and senior attending physician, Joseph H. Pratt Diagnostic Hospital, Boston. Second edition. 8<sup>o</sup> cloth. 741 pp., with 122 illustrations. Philadelphia: W. B. Saunders Company. 1947. \$3.00.

Dr. McCombs has thoroughly revised this new edition of his work first published in 1943 and has adhered to his original plan of providing a text in which basic principles of everyday problems in internal medicine are factually reviewed and controversial material omitted or strictly condensed. Special emphasis has been placed upon diseases in which errors in diagnosis and therapy commonly occur. Diagnostic and therapeutic methods most readily adaptable for use in general practice have been stressed. New chapters have been added on psychiatric disorders and on the common vascular disorders of the extremities. Chemotherapy has been completely rewritten to include the use and abuse of penicillin and streptomycin and their relation to the sulphonamides. New material includes lumbosacral sympathetomy in hypertension, the rice diet in hypertension and certain kidney diseases, high protein diets and protein hydrolyzates in malnutrition, folic acid in macrocytic anemias and sprue, serum albumin in circulatory failure and nephrotic conditions, gamma globulins in measles and infectious hepatitis, chloroquine in malaria, para-aminobenzoic acid in neketical diseases, thiouracil in hyperthyroidism, estrogen therapy and castration in cancer of the prostate, benadryl and pyrimethamine in allergic disorders, cytochrome C in anoxic states, indione in psychomotor disorders and heparin and dicumarol in vascular emergencies. A list of selected references is appended to each chapter and there is a good index. The book is well published in every way and should be in all medical libraries and should prove valuable to practicing physicians.

*An Introduction to Biochemistry*. By William R. Fearon, M.A., Sc.D., M.B., fellow of Trinity College and professor of biochemistry, University of Dublin; fellow of the Royal Institute of Chemistry and member of the Royal Irish Academy. Third edition. 8<sup>o</sup> cloth. 569 pp. Illustrated. New York: Grune and Stratton. 1947. \$6.00.

This third edition of a work first published in 1934 has been thoroughly revised and many new sections added. More emphasis has been placed on certain subjects of special interest in clinical medicine, including acid base balance, animal calorimetry, carbon dioxide transport, energy transformation, blood chemistry, bone formation, food absorption and detoxication. A chapter on tissue chemistry has been added and the chapter on nutrients has been rewritten. A good index completes the volume.

*Surgery of the Ambulatory Patient*. By L. Kreeger Ferguson, M.D., professor of surgery, Graduate School of the University of Pennsylvania; professor of surgery, Woman's Medical College of Pennsylvania; surgeon, Graduate Hospital of the University of Pennsylvania; Woman's Medical College Hospital, Philadelphia; General Hospital and Doctors Hospital and consulting surgeon, United States Naval Hospital. With a section on fractures by Louis Kaplan, M.D., associate in surgery, University of Pennsylvania; chief Surgical Service, Mt. Sinai Hospital, and in charge of the fracture division of the Surgical Out Patient department, Hospital of the University of Pennsylvania. Second edition. 8<sup>o</sup> cloth. 932 pp. with 645 illustrations. Philadelphia: J. B. Lippincott Company. 1947. \$10.00.

Dr. Ferguson, in revising his standard office surgery first published in 1942, has endeavored to bring up to date subjects in which definite progress has been made since the pub-

## CORRESPONDENCE

## BLOOD GROUPING FACILITIES IN JEOPARDY

*To the Editor* The following letter from Commissioner Vlado A. Getting discloses a situation that is distressing to many of us who appreciate the importance of the laboratory services offered by the Massachusetts Department of Public Health. It will be even more distressing when physicians and patients throughout the Commonwealth realize that this important assistance can no longer be obtained.

When the Executive Committee of the Blood Grouping Laboratory appropriated the money, two years in succession, to enable the state laboratory to perform Rh testing and blood grouping on blood samples submitted by physicians, particularly in prenatal cases, it was our desire to explore the usefulness of such testing as a public-health measure and to find out how many doctors would avail themselves of this free testing for the benefit of their patients. Scientifically, there can be no question that Rh typing and blood grouping are important, not only to the general public but more particularly to women during gestation. By knowing the blood group and Rh type, the physician can protect his patient against the hazards of emergency need for transfusion, which occurs suddenly as a complication of pregnancy from time to time, and can protect the infant, in certain cases, by helping establish promptly the diagnosis of erythroblastosis fetalis in the newborn and by providing immediate treatment. That this service by the state laboratory has been most useful is proved by the large number of doctors who have availed themselves of it, and by the fact that more than 1000 cases per month are now being tested. Certainly the peak has not been reached, and eventually it is quite possible that five or six times the present number of specimens would be sent to the State Laboratory if this work were permitted to continue. Unfortunately, the Blood Grouping Laboratory cannot continue to support from its research funds what is essentially a routine procedure, no matter how important this is as a public-health measure. It seems a pity, therefore, that this work should be allowed to lapse merely because its great value is not recognized by a committee of laymen.

I trust that this correspondence will help bring a distressing situation to the attention of physicians of the Commonwealth who recognize the need for this protective laboratory work, and that these physicians and their patients who have benefited will call the attention of their legislators to the error that will be made if the services of the state laboratory are curtailed in this respect.

Dr. Louis K. Diamond  
Blood Grouping Laboratory  
Children's Hospital  
300 Longwood Avenue  
Boston, Massachusetts

Dear Dr. Diamond

I am writing to inquire about the possibility of the continuation of a grant from your organization to provide Rh typing and blood grouping of bloods from pregnant women.

As you know, last year and this, the Department requested funds to carry on this service in its budget. The funds were not provided for the current year, and the item was not included in the Governor's budget, which was presented to the Legislature in January.

I had an opportunity to present this matter once more to the Ways and Means Committee a few days ago. I shall not know until the budget is passed whether further consideration will be given to this request, but because of the extraordinary demands being made upon the Legislature this year, it is altogether likely that the funds needed for this work will not be provided.

As you know, we were able to carry out over 9000 tests on pregnant women for physicians of the Commonwealth during the last twelve months. It will be quite a blow to the Department if it becomes necessary to curtail this service.

We are in essentially the same situation in diagnostic tests for virus diseases, which have been earned out in co-operation with the Virus Laboratory of the Harvard Medical School. Sufficient funds for the continuation of this work were not included in the expense item of the Division of Communicable Diseases in the budget submitted to the Legislature.

May I please hear from you regarding the possibility of continuing this service under a grant from your organization?

VLAO A. GETTING  
Commissioner

Commonwealth of Massachusetts  
Department of Public Health  
State House  
Boston

FURTHER COMMENT ON  
"UNNECESSARY OPERATIONS"

*To the Editor* I wish to subscribe to the comments made in the editorial "Unnecessary Operations," which appeared in the March 4 issue of the *Journal*. I imagine this editorial was written by one of your associates who is extremely well versed and qualified to comment on this subject. I simply wish to agree with statements and to add a comment or two based on my own experience.

The statistical improvement in mortality rates from appendicitis is most gratifying to everyone. The reasons for this improvement are, in my opinion, the result of better management of the individual patient and to a lesser extent better operative technique, and antibiotics and chemotherapy. It is not attributable to earlier or more accurate diagnosis so far as my observations indicate. Admissions to a specialized hospital for the young seem very much the same as they did fifteen years ago so far as appendiceal peritonitis is concerned. There has been an opportunity to observe admissions to two suburban and one Government hospital where the same situation obtains. My own experience in the past two years is similar.

I believe, therefore, that the article that inspired the editorial is capable of doing a great deal of harm. Relatively speaking, appendicitis is not a rare disease in childhood.

Prompt recognition of the disease is not common. Appendicitis is a diagnosis to be considered seriously when abdominal pain is a presenting symptom, and presence of localized tenderness, with or without supporting findings, is of the greatest importance. Home observation of such

NATIONAL GASTROENTEROLOGICAL  
ASSOCIATION

The thirteenth scientific session of the National Gastroenterological Association will be held at the Hotel Pennsylvania in New York City from June 7 to 10

In response to popular request the program this year will again for the most part consist of symposiums and there will be one panel discussion

The program for the first three days at the Hotel Pennsylvania will consist of symposiums on gastroduodenal ulcer, ulcerative colitis, jaundice and metabolism, nutrition and allergy. The panel discussion which will be followed by a question and answer period will cover the topics of diabetic, tuberculous, psychosomatic and cardiac manifestations in gastrointestinal diseases

The fourth day of the session will be devoted to clinics at co-operating hospitals in New York City

Further details and a copy of the program may be obtained by application in writing to the Secretary, National Gastroenterological Association, 1819 Broadway, New York 23, New York

## AMERICAN COLLEGE OF CHEST PHYSICIANS

The Board of Examiners of the American College of Chest Physicians announces that the next oral and written examinations for fellowship will be held at Chicago on June 17. Candidates who would like to take the examinations for fellowship in the college should communicate with the Executive Secretary, American College of Chest Physicians, 500 North Dearborn Street, Chicago 10, Illinois

The fourteenth annual meeting of the American College of Chest Physicians will be held at the Congress Hotel Chicago from June 17 to 20

STUDENTS INTERNATIONAL CLINICAL  
CONGRESS

The International Union of Students and the British Medical Students Association invite a delegation of fifteen medical students from the United States of America to a Students International Clinical Congress of 200 delegates to be held in England from July 6 to 24. Lectures, seminars

Figure 5, which shows, not for all medication common to the range dosage in milligrams per day, that the daily dosage was very consistently, smaller for all the normal records. Figure 5 also shows an unexpected result that 40 patients with normal records had discontinued all anticonvulsive medicine by the time

FIGURE 5 Medication in All Patients with Normal Electroencephalogram and in Selected Patients with Abnormal Tracings

The columns with notched tops represent patients given alternative dosages of medicine (such as one or two tablets of mebaral), the lower level of the notch representing the smallest and the higher level the largest average dosage determined by such alternatives. The various types of anticonvulsants prescribed are indicated as follows: P = phenobarbital, D = diphenylhydantoin sodium (dilantin), and M = mebaral.

of the last visit, whereas this was true for only 1 of the 38 selected abnormal group.

A detailed analysis was made of the case data on the 8 patients who, up to the last visit, had successfully discontinued anticonvulsive medication. This analysis suggests that the prognosis for remission of seizures off medicine is favorable under the following conditions: if the patient has had no attacks in infancy, if he shows, other than seizures, no evidence of encephalopathy, if he has been so mildly disturbed and is so well endowed as to have maintained a good social adjustment despite the seizures, if he presents, at the time that withdrawal of medicine is considered, a normal electroencephalogram (perhaps preferably done while the patient is off anticonvulsants for at least forty-eight hours), and if he has been seizure free for a period of one to two years, with anticonvulsants gradually reduced to, and maintained at, a minimal dosage of 1 capsule or tablet of phenobarbital, mebaral or dilantin daily or every other day for three months. The bias of this paper leads to a special emphasis on the normal record as a favorable criterion. A negative family history for epilepsy may also be prognostically

favorable. Probably, too, a relatively low maximal incidence of seizures—perhaps less than about twelve seizures a year at the worst period—is favorable. Apparently little prognostic significance attaches to the age at onset for the chronic adult epilepsy, as distinguished from attacks in infancy, the type of seizure or the relative incidence of seizures while the patient is awake and asleep. Finally, it may be added that remission of seizures off medicine is common in the late teens and early twenties.

Regarding the number of seizures while the patient is awake as compared with the number while he is asleep, whether at night in bed or during a daytime nap, one gets the clinical impression that the proportion of seizures while the patient is asleep is higher among patients with normal than among those with abnormal electroencephalograms. This impression appears to be confirmed by the analysis shown in Figure 6. In each group the clinical histories on 40 per cent of the patients failed to indicate any seizures in sleep. For the remaining 55 per cent of each of the two groups, Figure 6 shows a favorable trend toward a relatively higher incidence of seizures in sleep among patients having normal as compared with those having abnormal records.

These patients were also studied for four other features, which are described without graphic representation.

Thus, there was little contrast between the two groups regarding the occurrence of convulsions in

FIGURE 6 Occurrence of Seizures during Sleep

infancy—convulsions, that is, in the first five years of life and separated from the chronic adult epilepsy by a long, seizure-free period. Among the patients with normal records, there were 4, or 10 per cent, and among the selected abnormal group, there were 5, or 13 per cent, who gave a history of such infantile convulsions.

There was also little contrast between the two groups in the occurrence of post-traumatic or other encephalopathies, as distinguished from mere electrocortical abnormality. By implication or direct evidence, such encephalopathies were present in 15, or 33 per cent, of the 40 patients with normal and in 14, or 37 per cent, of the 38 selected patients with abnormal electroencephalograms.

#### RESEARCH COUNCIL GRANTS FOR RESEARCH

The Committee on Human Reproduction of the National Research Council, acting for the National Committee on Maternal Health, Inc., announces that grants for research in the field of reproduction are available. Applications to become effective July 1, 1948, will be received until May 1, 1948, applications to become effective October 1, 1948, will be received until August 1, 1948.

The committee will consider support of biologic, clinical, economic, medical, psychologic and sociologic research dealing broadly with the field of human reproduction in general and with specific problems, including maternal and fetal physiology, the factors controlling conception, the physiology of fertilization and conception, and sterility. For the year 1948-1949, the committee will place specific emphasis upon investigations of the factors controlling conception, fertility and sterility, but other fields of endeavor will be supported if projects of special significance are presented. In subsequent years, changing emphasis may be anticipated.

The National Committee on Maternal Health has advised the National Research Council that it proposes to solicit funds to finance the program of research recommended by the Committee on Human Reproduction to an amount of approximately \$200,000 for 1948-1949.

Communications regarding grants should be addressed to Committee on Human Reproduction, National Research Council, 2101 Constitution Avenue, N W, Washington 25, D C

 FRACTURES

May 26 to May 29 1948 Inclusive

Dr Reginald Watson-Jones of London, England, will conduct the four-day full time course at the Boston City Hospital assisted by the leading surgeons of the Orthopedic Department. The subjects covered will be common fractures of the long bones of both extremities and of the spine, complicated and fracture dislocations of the common joint, principles of bone grafting and principles of internal fixation of fractures. Tuition fee \$20. Veterans may enroll under the Civil Bill of Rights. Apply to Miss Louise Murray, Secretary, Fifth Surgical Service, Boston City Hospital, 115 Harrison Avenue, Boston, Massachusetts, enclosing a check or money order payable to Trustees of Tufts College.

# BACKGROUND

The use of cow's milk, water and carbohydrate mixtures represents the one system of

infant feeding that consistently, for over three decades, has received universal pediatric

recognition. No carbohydrate employed in this system of infant feeding enjoys so rich and enduring a background of authoritative clinical experience as Dextri-Maltose.

## SOME CLINICAL ASPECTS OF THE NORMAL ELECTROENCEPHALOGRAM IN EPILEPSY\*

JOHN A. ABBOTT, M.D.,† AND ROBERT S. SCHWAB, M.D.†

BOSTON

WHAT does it mean if the electroencephalogram of an epileptic patient is normal between seizures? On the one hand, the physician may have been led to believe that an abnormal electroencephalogram is highly characteristic of epilepsy. On the other hand, if he regularly refers his epileptic patients for electroencephalographic study, he forms the impression that, for a goodly portion of them, the tracings, at least at the time of examination, which is almost always done between seizures, are described as normal. This may be true even for patients examined when not taking anticonvulsive medicine.

Statistically, a review of the literature shows that the reported incidence of epileptic patients with normal electroencephalograms between seizures ranges from around 2 per cent to around 20 per cent. Historically, the smaller percentages seem to have been reported by the pioneer investigators. Thus Lennox, Gibbs and Gibbs,<sup>1</sup> in 1940, make incidental allusion to a series, perhaps not unselected, of 94 cases, in which the electroencephalograms were normal in only 2.2 per cent, whereas in a later study, published in 1941, Gibbs and Gibbs say that "in our experience less than five per cent of patients clearly diagnosed as epileptic have an initial record which is clearly normal." In 1941 Jasper and Kershman<sup>2</sup> reported a group of 494 patients with symptoms recognized clinically as epileptic, among whom only 26, or about 5 per cent, gave electroencephalograms in which "no obvious abnormality could be seen." In 1943 Solomon et al.<sup>3</sup> reported that, of 121 Navy recruits rejected with the diagnosis of epilepsy, 22 per cent had normal electroencephalograms. In 1944 Echlin<sup>4</sup> observed that the records were normal in 20 per cent of 100 epileptic patients. Hughes,<sup>5</sup> in 1944, reported that "a single electroencephalogram will give positive evidence of epilepsy in about 80 per cent of cases." In the same year Lambros, Case and Walker<sup>6</sup> stated

that, without hyperventilation, the records were abnormal in 75 per cent of patients with clinical evidence of epilepsy. Lennox,<sup>1</sup> in 1945, reported that in his series the electroencephalograms were normal in 18 per cent of patients with grand-mal seizures, 15 per cent with psychomotor seizures and 8 per cent with petit-mal seizures. In 1946 Baudoin, Fischgold and Remond<sup>7</sup> reported a 20 per cent incidence of normal records among epileptic patients examined between seizures. In our own series, discussed below, normal electroencephalograms were noted in 21 per cent of the patients examined between seizures.

So high an incidence of normal electroencephalograms among these patients makes obviously urgent an answer to the question asked at the beginning of this paper. The purpose of this communication is to report at least an initial, tentative and partial answer to that question.

This paper is based on the study of 193 patients attending the Epileptic Clinic of the Nerve Out-Patient Department at the Massachusetts General Hospital. Attendance at the clinic is restricted to patients ten to twelve years old or older. These patients were selected from the total attendance in accordance with only two criteria: the clinical diagnosis of epilepsy should be unequivocal, and for each patient at least one record should have been taken in accordance with a well standardized electroencephalographic procedure.

So far as technical details are concerned, electroencephalograms were recorded on a three-channel or six-channel Grass inkwriting oscillograph of the generally familiar type. In each case six or sixteen scalp electrodes were applied, in addition to two mastoid or ear-lobe electrodes, recordings were made from an extensive variety of scalp-to-scalp (so-called "bipolar") as well as of scalp-to-mastoid-or-ear-lobe (so-called "monopolar") linkages, at the end, the patient was hyperventilated for three minutes and observed for one minute after hyperventilation, and the whole recording was run for about thirty minutes. At the time of the test notes were made whether or not the patient was fasting and had been

†Instructor in Neurology, Harvard Medical School.

Figure 5, which shows, not for all medication common to the average dosage in milligrams per that the daily dosage was very consistently, smaller for all the normal records. Figure 5 also and unexpected result that of the 40 patients with normal records had discontinued all anticonvulsive medicine by the time

FIGURE 5 Medication in All Patients with Normal Electroencephalogram and in Selected Patients with Abnormal Tracings

The columns with notched tops represent patients given alternative dosages of medicine (such as one or two tablets of mebaral), the lower level of the notch representing the smallest and the higher level the largest average dosage determined by such alternatives. The various types of anticonvulsants prescribed are indicated as follows: P = phenobarbital, D = diphenylhydantoin sodium (dilatantin), and M = mebaral.

of the last visit, whereas this was true for only 1 of the 38 selected abnormal group.

A detailed analysis was made of the case data on the 8 patients who, up to the last visit, had successfully discontinued anticonvulsive medication. This analysis suggests that the prognosis for remission of seizures off medicine is favorable under the following conditions: if the patient has had no attacks in infancy, if he shows, other than seizures, no evidence of encephalopathy, if he has been so mildly disturbed and is so well endowed as to have maintained a good social adjustment despite the seizures, if he presents, at the time that withdrawal of medicine is considered, a normal electroencephalogram (perhaps preferably done while the patient is off anticonvulsants for at least forty-eight hours), and if he has been seizure free for a period of one to two years, with anticonvulsants gradually reduced to, and maintained at, a minimal dosage of 1 capsule or tablet of phenobarbital, mebaral or dilatantin daily or every other day for three months. The bias of this paper leads to a special emphasis on the normal record as a favorable criterion. A negative family history for epilepsy may also be prognostically

favorable. Probably, too, a relatively low maximal incidence of seizures—perhaps less than about twelve seizures a year at the worst period—is favorable. Apparently little prognostic significance attaches to the age at onset for the chronic adult epilepsy, as distinguished from attacks in infancy, the type of seizure or the relative incidence of seizures while the patient is awake and asleep. Finally, it may be added that remission of seizures off medicine is common in the late teens and early twenties.

Regarding the number of seizures while the patient is awake as compared with the number while he is asleep, whether at night in bed or during a daytime nap, one gets the clinical impression that the proportion of seizures while the patient is asleep is higher among patients with normal than among those with abnormal electroencephalograms. This impression appears to be confirmed by the analysis shown in Figure 6. In each group the clinical histories on 45 per cent of the patients failed to indicate any seizures in sleep. For the remaining 55 per cent in each of the two groups, Figure 6 shows a favorable trend toward a relatively higher incidence of seizures in sleep among patients having normal as compared with those having abnormal records.

These patients were also studied for four other features, which are described without graphic representation.

Thus, there was little contrast between the two groups regarding the occurrence of convulsions in

FIGURE 6 Occurrence of Seizures during Sleep

infancy—convulsions, that is, in the first five years of life and separated from the chronic adult epilepsy by a long, seizure-free period. Among the patients with normal records, there were 4, or 10 per cent, and among the selected abnormal group, there were 5, or 13 per cent, who gave a history of such infantile convulsions.

There was also little contrast between the two groups in the occurrence of post-traumatic or other encephalopathies, as distinguished from mere electrocortical abnormality. By implication or direct evidence, such encephalopathies were present in 13, or 33 per cent, of the 40 patients with normal and in 14, or 37 per cent, of the 38 selected patients with abnormal electroencephalograms.

Seven patients, or 18 per cent, with normal and 10, or 26 per cent, with abnormal records gave a positive family history of epilepsy.

In the three preceding comparisons, the differences were slight, but it may be significant that they were all in favor of the group with normal electroencephalograms.

Among the differences not represented graphically, however, a striking contrast between the two groups of patients appeared in the scholastic and occupational histories. Among those with normal records only 4, or 10 per cent, had been put out of school or had lost or changed jobs, or were unemployed because of their epilepsy, whereas 11, or 28 per cent, among the selected abnormal group had been put out of school or had lost jobs or were chronically unemployed or unemployable.

### DISCUSSION

From the observations cited above, it seems reasonable to conclude that a normal or almost normal electroencephalogram should be prognostically favorable and so of practical value, especially if it is recorded at the time of the first seizures when the future course of the illness is still unpredictable, whereas a grossly abnormal record should serve usefully to forewarn the physician of future difficulties and disappointments or to explain such difficulties and disappointments if they are already established.

### SUMMARY

Epileptic patients each showing at least one normal electroencephalogram between seizures and those showing only abnormal electroencephalograms between seizures are compared with reference to ten other aspects of the disease. All ten comparisons are favorable to the patients with normal records. In the patients with normal electroencephalograms there were later onset, fewer different kinds of spells, less frequent spells, greater response to medicine, more remissions while off medicine, more spells during sleep and greater ability to work, whereas patients with abnormal records had had spells in infancy, head injuries or other encephalopathies and positive family history of epilepsy.

## SPONTANEOUS PNEUMOTHORAX\*

### A Clinical Study of One Hundred Consecutive Cases

RALPH M. MYERSON, M.D.†

BOSTON

IT IS the purpose of this paper to present 100 consecutive, unselected cases of spontaneous pneumothorax in patients admitted to the Boston City Hospital in a nine-year period between 1934 and 1943. During the same period approximately 375,000 patients were admitted to the hospital, giving an incidence of 0.027 per cent, a figure that coincides with that of the series of Cohen and Kinsman.<sup>1</sup>

### DIAGNOSIS

The diagnosis in each case was made on the basis of the history, physical signs and x-ray findings. Positive x-ray findings were considered essential, and the diagnosis was not made in their absence.

The patients were divided into two groups, one consisting of 64 cases in which underlying pulmonary disease was known prior to entry or discovered during hospitalization, and the other com-

prising 36 cases of spontaneous pneumothorax occurring in apparently healthy persons. The older literature attributed a much higher percentage of spontaneous pneumothorax to underlying pulmonary lesions, especially tuberculosis. Of 918 cases collected by Biach,<sup>2</sup> 77.8 per cent were said to be due to tuberculosis. Morse<sup>3</sup> attributed 70 per cent of his 51 cases to tuberculosis, and Ayer<sup>4</sup> 69 per cent of his 72 cases, and West<sup>5</sup> found 99 of his 101 reported cases due to tuberculosis. However, the last series was derived from patients hospitalized for chronic lung diseases. As recently as 1931, Palmer and Taft<sup>6</sup> could find only 70 reported cases of spontaneous pneumothorax occurring in apparently healthy persons. Kjaergaard<sup>7</sup> focused attention on this condition with his monumental series in 1932.

### CLINICAL PICTURE

The history, symptoms and signs presented by the patients of both groups were essentially the same.

\*From the First Medical Service (T-61), Boston City Hospital.  
†Chief resident, First Medical Service, Boston City Hospital.

Of both groups gave a history of prior to the acute episode. Of history of strenuous lifting, 4 of lifting, 3 of running upstairs, 2 of and 1 each of wrestling, playing pat, missing a step going down-an automobile. In the remaining 80 per cent the pneumothorax occurred during usual daily activities or at rest. In their series of 58 cases Ornstein and Lercher<sup>8</sup> found a history of exertion in 22 per cent.

Chest pain occurred in every patient and was always localized to the involved lung, with occa-

have been expected, there was a preponderance of cases in males except in the acute disorders, in which the ratio of males to females was about 1:1. The patients in this group ranged in age from twelve to eighty-two years, with an average age of forty-six years and one month. This is, in marked contrast to the patients in the second group, who had an average age of twenty-seven years and one month, with a range of three to fifty-three years.

The occurrence of a spontaneous pneumothorax in a patient above the age of forty-five should make one strongly suspicious of the presence of under-

TABLE 1 Incidence of Underlying Pulmonary Disorders in 64 Patients with Spontaneous Pneumothorax

sional radiation to the abdomen, neck or lower back. Dyspnea was also universally complained of, but frequently appeared to be more subjective than objective. Cough and fever were common in patients of the first group, but only 5 patients in the second complained of cough, and only 3 had an elevated temperature, which was slight. Hemoptysis occurred in 2 patients with underlying tuberculosis.

The physical signs varied with the degree of lung collapse. It was generally found that when the degree of pneumothorax was more than 40 per cent, classic signs could be elicited. These included hyperresonance, diminished or absent vocal and tactile fremitus, absent breath sounds, mediastinal shift and positive coin test. The physical signs may be scant or absent in the presence of small pneumothoraces. In the first group the additional findings of the underlying pulmonary lesion were also present. Right-sided and left-sided pneumothorax occurred with equal frequency in both groups. One patient with bilateral spontaneous pneumothorax had far advanced bilateral tuberculosis.

#### ASSOCIATED PULMONARY DISEASE

Table 1 shows the incidence of the various pulmonary disorders that were found associated with the patients in the first group. Tuberculosis constituted the underlying cause in 50 per cent of this group and in 38 per cent of the total. As might

lying pulmonary disease. The following case illustrates this point.

K. H. (B. C. H. 1129821), a 53-year-old man, was admitted to the hospital in May, 1943. He had been perfectly well until 2 hours prior to entry, when he noticed a sudden, sharp, right-sided pleuritic chest pain accompanied by dyspnea. Physical examination revealed classic signs of a right pneumothorax and was otherwise negative. Two x-ray films of the chest confirmed the presence of a 50 per cent pneumothorax on the right. An area of patchy density was described in the collapsed right upper lobe.

Examination of the blood revealed a red-cell count of 4,720,000, with a hemoglobin of 14 gm., and a white-cell count of 9000, with 79 per cent neutrophils, 18 per cent lymphocytes and 3 per cent monocytes. The blood sedimentation rate was 15 mm per hour. Two urinalyses were negative.

The patient left the hospital against advice on the 6th hospital day before further investigation could be carried out.

He was readmitted 14 months later with a 10-week history of cough, right-sided chest pain radiating down the right arm, progressive weakness, anorexia and a weight loss of 25 pounds. Physical examination revealed a Horner's syndrome on the right, signs of a mass in the right upper lung and a mediastinal shift to the left. A large tender mass was palpated in the right flank. Laboratory studies were negative except for a moderate degree of anemia.

The patient went downhill rapidly and died 3 weeks after admission. Autopsy revealed a renal-cell carcinoma of the right kidney, with metastases to the left adrenal gland and right lung.

In this case the spontaneous pneumothorax undoubtedly represented the lung metastasis, and since renal-cell carcinoma tends toward solitary metas-

tases, it is interesting to speculate whether early diagnosis might have prolonged the patient's life

### SPONTANEOUS PNEUMOTHORAX IN APPARENTLY HEALTHY PERSONS

Of the 36 cases in the second group 30, or 83.3 per cent, occurred in male patients. This predilection has been reported by all previous investigators. As stated above, there was an age range of three to fifty-three years, with an average age of twenty-seven years and one month. Table 2 shows the contrast of age incidence by decades between the two groups.

Of the 36 patients in the second group 21 were successfully followed for periods ranging from one and a half to twelve years. Of these, 2 had died of other causes. 1 of cirrhosis of the liver five years after the occurrence of the pneumothorax, and the other of acute yellow atrophy of the liver two and a half years after the original attack. Post-mortem examination of the lungs in the latter case was reported as negative.

Three patients had multiple recurrences — an incidence of 14.3 per cent (in other series a recurrence rate of 10 to 30 per cent has been reported<sup>4</sup>). One of these 3 patients had multiple attacks, estimated by the patient as numbering eighteen to twenty. Chest x-ray study was negative six and a half years after the original attack, and the patient was considered a candidate for the induction of a chemical pleuritis. One female patient had a total of seven recurrences and had a negative x-ray examination twelve years after the original attack. The third patient in this group had a total of seven recurrences. Between the fourth and fifth attacks he developed clinical and x-ray evidence of tuberculosis and he died three and a half years after the first occurrence of pneumothorax. After the first four episodes the lung fields had appeared clear after re-expansion, and during the first and second admissions tuberculin tests had been negative in dilutions of 1:100. This patient represents the only one in the second group who was known to have developed tuberculosis. Kjaergaard<sup>7</sup> followed 49 patients of this type and found only 1 who developed tuberculosis subsequent to spontaneous pneumothorax. In a review of the literature Perry<sup>8</sup> could find a record of only 6 cases developing tuberculosis after a benign spontaneous pneumothorax.

One patient had a typical attack of spontaneous mediastinal emphysema 3 years after the first occurrence of pneumothorax and was alive and well nine years later.

### TREATMENT

All patients were treated with bed rest and symptomatic medication to relieve pain and cough. Aspiration of air to relieve dyspnea was done in 3 cases. Whenever possible, appropriate therapy was directed toward the underlying condition in patients in the first group. Patients with tubercu-

losis were transferred to sanatoriums shortly after admission. Hospitalization of patients in the second group varied from two to thirty-six days, with an average stay of eleven days. There was no immediate mortality in this group. Four patients in the first group expired during the hospital stay.

### SUMMARY AND CONCLUSIONS

One hundred cases of spontaneous pneumothorax in patients admitted to the Boston City Hospital between 1934 and 1943 are presented. Of these,

TABLE 2 Comparison of Age Incidence of Spontaneous Pneumothorax in Patients with Underlying Pulmonary Disease and in Apparently Healthy Persons

AGE yr	PATIENTS WITH UNDERLYING PULMONARY DISEASE		APPARENTLY HEALTHY PERSONS	
	NO.	PERCENTAGE	NO.	PERCENTAGE
0-9	0	0	1	2.8
10-19	4	6.3	7	19.4
20-29	9	14.0	17	47.2
30-39	12	18.8	5	13.9
40-49	10	15.6	5	13.9
50-59	13	20.3	1	2.8
60-69	11	17.2	0	0
70-79	3	4.7	0	0
80-89	2	3.1	0	0
Totals	64		56	

64 patients, with an average age of forty-six years and one month, had underlying pulmonary disease, of which tuberculosis constituted 59 per cent.

Thirty-six cases occurred in apparently healthy persons with an average age of twenty-seven years and one month, 21 of whom were successfully followed for periods of one and a half to twelve years. Three patients, or 14.3 per cent, had recurrences. One had a subsequent attack of spontaneous mediastinal emphysema. Another developed tuberculosis after four recurrences.

A comparison of the history and clinical signs and symptoms in the two groups is presented.

The occurrence of a spontaneous pneumothorax in a person over forty-five years of age should excite suspicion of an underlying pulmonary lesion. A case is presented to illustrate this point.

The prognosis in the apparently healthy person with a spontaneous pneumothorax is excellent from the standpoint of both immediate recovery and the subsequent development of tuberculosis.

## STREPTOMYCIN TREATMENT OF BACTERIAL ENDOCARDITIS\*

## Report of a Case

BENEDICT F MASSELL, M D,† J WALLACE ZELLER, M D,‡ JAMES W DOW, M D,\$ AND  
DONALD HARTING, M D ¶

With the Technical Assistance of Mary Meyeserian||

BOSTON

A CASE of bacterial endocarditis due to a gram-negative organism belonging to the genus *Hemophilus* is reported for two reasons: it is one of the early reported recoveries following treatment with streptomycin—perhaps the first patient of this kind to recover without any other therapy, and recovery followed a shorter course of treatment than would ordinarily be planned.

## CASE REPORT

S K, a 9-year-old girl, entered the House of the Good Samaritan on June 28, 1946, complaining of fever of about 3 months' duration. Her birth and early development were thought to have been normal. At 4 years of age she experienced an attack of fever accompanied by migratory joint pain. From that time on she was thought to tire easily, to be short of breath, and to become blue on climbing a flight of stairs. The physician who referred her to the hospital first saw her when she was 6 years old. He observed her to be cyanotic, to have an enlarged heart by physical examination and by fluoroscopy, and to have a hemoglobin of 13.5 gm. Despite these findings she remained in fair health for the next 2 years.

On April 27, 1946, the patient returned to the physician's office complaining of fever of an indefinite duration. Examination showed her to be intensely cyanotic, with a liver edge palpable 4 fingerbreadths below the costal margin and with an enlarged spleen. She was admitted to another hospital 2 days later. At that institution the hemoglobin was 12.7 gm, the red-cell count 4,300,000, and the white-cell count 14,200. The heart was enlarged by x-ray study. Three blood cultures grew no organism. For 1 month of hospitalization the course was febrile, with daily oral temperature elevations to 102°F. The physical findings did not change. From discharge on May 24 until her admission to the House of the Good Samaritan she remained in bed at home, where she continued to run a fever. On one or more occasions during this period there were minor hemoptyses.

Physical examination disclosed a thin, pale child, who was small for her age and moderately cyanotic. The weight was 50 pounds. There was minimal clubbing of the fingers and toes. The heart was large, with a forceful, apical impulse for a maximum of 7 cm from the midsternal line in the fourth intercostal space, 1.5 cm outside the midclavicular line. Dullness to percussion was detected well out in the second and third left interspaces. There was a Grade IV to Grade V, rough, systolic murmur and thrill maximum in the first and second left interspaces. The murmur was well transmitted to the apex, neck and interscapular region and tended to mask the basal but not the apical heart sounds. There was a loud, diastolic, third heart sound, but no diastolic murmur. Arterial and venous cervical pulsations were present with the patient erect. The blood pressure was 125/80, and femoral pulsations were strong. The liver edge was felt 4 cm below the costal

margin but was not tender. The spleen was easily palpable. No petechiae were seen, nor were Osler's nodes demonstrated.

Examination of the urinary sediment revealed 15 to 20 red cells per high-power field. The red-cell count was 4,960,000, with a hemoglobin of 11.8 gm, and the hematocrit was 40 per cent. The white-cell count was 11,600. The corrected sedimentation rate by the Ernestine-Rourke method was 1.5 mm per minute (normal, 0.05 to 0.40 mm per minute). Agglutinations for brucellosis and typhoid fever were negative. The electrocardiogram was typical of extreme right-sided heart strain. Fluoroscopy showed the heart to be large, with a massive right ventricle and dilated main pulmonary artery, but small intrapulmonary branches and an inconspicuous aortic knob.

From admission until specific treatment was begun on July 19 the patient ran a fever, the rectal temperatures spiking daily to 103°F at 4:00 p.m. and falling to 96°F each morning at 8:00 o'clock. The blood was cultured on June 28, on July 1 and 2 and again just before treatment was started.

on July 19. In all, fourteen flasks were inoculated, and in every one there grew out a small, gram-negative, coccobacillus.

This micro-organism was studied in some detail by George E. Foley, of the Children's Hospital, Boston, who found that it presented the morphologic, cultural and biochemical characteristics of the genus *Hemophilus*. It did not agglutinate with *Haemophilus influenzae* antisera, Types A through F. Its ability to grow in mediums without hematin (X factor) but not in those without yeast (V factor) was interpreted as being typical for *H. parainfluenzae*.<sup>1</sup>

Sensitivity of the organism to known concentrations of penicillin and streptomycin was determined on blood-agar plates rather than in dextrose broth, in which the organism grew very poorly. A control organism of known penicillin sensitivity (when tested in broth) was found to be inhibited with the expected concentration of penicillin on the blood-agar medium.

Growth of the organism was not inhibited by concentrations of penicillin as high as 10 units per cubic centimeter. Streptomycin inhibited growth in concentrations greater than 2 units and less than 4 units per cubic centimeter. These results indicated that *in vitro* the organism was resistant to penicillin but sensitive to concentrations of streptomycin easily obtainable in the blood. Table 1 shows that serum streptomycin concentrations from five to fifteen times that required to inhibit the organism *in vitro* were actually obtained during therapy.

||Technician, House of the Good Samaritan.

On July 19 treatment was started with 2 gm. of streptomycin daily given in eight divided doses at 3 hour intervals by intramuscular injection. The course planned was to extend over a 14-day period, during which the patient was to receive a total of 28 gm. of the drug. The septic fever broke immediately after the first dose. Blood cultures taken 18 hours after the start of therapy those made while on treatment and those taken as late as 2 months after the end of therapy showed no growth (Fig 1).

The patient improved during the first 5 days of treatment until it became necessary to use a different brand of

infections are by members of the genus *Hemophilus*. Thayer<sup>2</sup> implicated this group in 29 per cent of all cases of infective endocarditis. As in bacterial endocarditis due to the *Streptococcus viridans*, infection is always implanted on a congenital defect or previously damaged cardiac valve, and the clinical manifestations, course and prognosis of the untreated disease are the same with either organism.<sup>2-5</sup>

FIGURE 1 Temperature Streptomycin Dosage and Blood Cultures in a Case of Bacterial Endocarditis

streptomycin. The second lot caused fever with rectal temperatures sustained between 101 and 103 F and local irritation so severe that treatment had to be discontinued after a total of only 13.5 gm. had been given in 634 days. There was no other evidence of a toxic reaction to the drug.

After omission of therapy the temperature fell by lysis in 4 days. The patient improved steadily and uneventfully except for a small hemoptysis on July 28. She gained 13 pounds and seemed entirely well at time of discharge on November 24. Although the liver became smaller the spleen remained palpable throughout hospitalization.

During convalescence the red-cell count rose to 5 750 000, the hemoglobin to 16.3 gm. and the hematocrit to 54 per cent, although with the disappearance of the signs of heart failure cyanosis became minimal. These high values supported the possible diagnosis of an underlying cardiac anomaly consisting of a right-to-left shunt. Consequently the patient was referred to Dr. Lewis Dexter and his associates at the Peter Bent Brigham Hospital for study by venous catheterization. Dr. Dexter's findings were consistent with a high degree of pulmonary stenosis together with a small ventricular septal defect and probable overriding aorta. The Blalock operation was not advised by Dr. Dexter because the oxygen saturation of the peripheral arterial blood was found to be high (87 per cent).

The patient was well and active at the time of writing 1 year after the completion of therapy.

#### DISCUSSION

Gram-negative bacilli are only occasionally the agents causing bacterial endocarditis. Of the small proportion of endocarditides so caused most of the

Craven, Poston and Organ,<sup>3</sup> in 1940, were unable to find a report of a case due to an influenzal or parainfluenzal organism in which the patient recovered.

Since 1941 apparent cures have been reported in 8 patients treated with sulfonamides and antibiotics.<sup>4-6</sup> Of 2 cases treated at Mount Sinai Hospital, 1 was arrested with a sulfonamide alone, whereas the other responded to sulfapyridine and hyperthermia.<sup>4</sup> After each had proved ineffective alone, penicillin and sulfamerazine combined sterilized the blood of a patient reported by Priest and McGee.<sup>7</sup> Of 2 cases reported by Hunter and Duane,<sup>8</sup> 1 yielded to sulfadiazine after penicillin had failed. The second patient recovered after penicillin, sulfadiazine and streptomycin had been used.<sup>8</sup> Streptomycin may well have been the effective agent in this case, but unfortunately three blood cultures taken before streptomycin was started remained sterile.

More recently Hunter<sup>8</sup> added 2 cases from his own experience and 5 more supplied to him by Dr. Chester Keefer. In these 7 cases, 3 patients have survived. Each of the survivors received penicillin or a sulfonamide prior to or in conjunction with

streptomycin, although the latter was credited with the favorable outcome

A much wider experience is available in the treatment with streptomycin of influenzal and para-influenzal infections of other systems. The drug has proved to be effective in meningitis, pulmonary disease, bacteremia and urinary-tract infection<sup>10-12</sup>. Unfortunately, its usefulness has been limited by the rapid development of organism resistance when the concentration of the drug at the site of the lesion is inadequate and by the toxic effects that have lately become apparent.

Deliberate attempts to increase the resistance of gonococci to streptomycin in vitro have resulted in tolerance by the organism of from 1900 to perhaps as much as 75,000 times the originally effective concentration.<sup>13</sup> This demonstration has been paralleled clinically with *H. influenzae* infections, as well as with infections due to other organisms.<sup>14, 15</sup> In these cases loss of therapeutic effect has been associated with a decreased sensitivity of successively isolated organisms. In 1946 Keefer<sup>11</sup> considered it advisable to maintain at the lesion a concentration of streptomycin from four to eight times that required to inhibit the organism in vitro so that infection could be eradicated before resistance to the drug developed. No patient in Hunter's<sup>9</sup> group recovered if a concentration greater than 8 microgm of streptomycin per cubic centimeter was required to inhibit the causative organism in vitro.

The important toxic manifestation is severe and possibly permanent eighth-nerve damage, with not only vestibular dysfunction but also nerve deafness.<sup>16</sup> Damage increases with both the amounts of streptomycin given and the period of administration. Histamine-like reactions may be effectively treated with benadryl or pyribenzamine, and local irritation is not a problem with pure preparations.

It is apparent that high concentrations of streptomycin are desirable from the start, that if resistant strains appear, prolonged treatment may be useless, and that the longer the treatment, the greater the risk of vestibular damage and nerve deafness. If effective a short, intensive course should theoretically be ideal. Hunter recommends three or four weeks of treatment with 2 to 6 gm of streptomycin daily, with the reservation that if the case is clinically favorable and nerve deafness is developing the drug

may be stopped after two weeks. It is of interest that the patient in the case reported above recovered after only six and a half days of treatment.

### SUMMARY

Streptomycin was an effective agent for treatment in a case of endocarditis caused by a gram-negative organism belonging to the genus *Hemophilus*.

The causative organism was isolated and its sensitivity to the drug in vitro determined before treatment was started.

The concentration of streptomycin maintained in the blood was never less than twice and rose as high as fifteen times that required to inhibit the organism in vitro.

A short, intensive course of streptomycin eradicated the infection in this case.

We are indebted to George E. Foley and Commander L. A. Barnes, H (S), USNR, for their identification of the organism, and to Dr. Norman Pokorny, who diagnosed the disease and referred the patient for treatment.

## MALARIA\*

## Observations on Treatment with Chloroquine (SN 7618) and Combined Quinine and Plasmochin

THOMAS A. WARTHIN, M.D.,† SIDNEY A. LEVINE, M.D.,‡ AND RICHARD R. EVANS, M.D.†

WEST ROXBURY, MASSACHUSETTS

NUMEROUS excellent descriptions of the clinical symptomatology, course and response to quinacrine (atahrine) therapy of relapsing vivax malaria of Pacific origin have appeared in the last four years. Most and his associates<sup>1</sup> have described the effects on the relapse rate of combined quinine and plasmochin treatment. Similar but less complete studies have been made by Bianco and his co-workers<sup>2</sup> and others. Loeh,<sup>3</sup> Most et al.<sup>4</sup> and Faust<sup>5</sup> have described the early results of treatment with chloroquine (SN 7618). All these studies were carried out in the various military services, with the patients usually hospitalized throughout the entire period of therapy and follow-up observation. It was believed, therefore, that a longer post-therapeutic follow-up period of patients who had been living under ordinary civilian conditions would prove of value, and that general trends in the course of the infection might be of interest to the practitioner.

## MATERIALS AND METHODS

During the year of July 1, 1946, to July 1, 1947, 125 patients with proved malaria due to *Plasmodium vivax*, all of Pacific origin, were admitted to the Veterans Administration Hospital, West Roxbury, Massachusetts. All had received suppressive quinacrine therapy while stationed in malarial zones, and most had been given various doses of quinacrine for prior clinical attacks. Once a positive smear had been obtained, either of two methods of treatment was offered. Those who desired as short a period of hospitalization as possible were treated with chloroquine diphosphate. The dosage was 1.0 gm. (4 tablets, each containing 0.25 gm. of the diphosphate) followed in eight hours by 0.5 gm. (2 tablets). A single dose of 0.5 gm. was administered on the second and third days of treatment. Most patients were discharged on that day, with instructions to take 0.5 gm. (2 tablets) every Sunday for five weeks. Out-patient follow-up physical examinations with smears for malarial parasites and an extensive symptomatic history were obtained every two months. If an unusual clinical finding such as a

positive serologic test had been noted, the checkups were made on a monthly basis.

Patients who complained of over five recurrent attacks of malaria and those who were able to spend two weeks in the hospital were placed on the combined quinine-plasmochin regime as outlined by Most et al.<sup>1</sup> Plasmochin naphthoate, in 0.02-gm doses, was administered every eight hours for fourteen days. Quinine sulfate was prescribed in 1.0-gm doses every eight hours for one day followed by 0.6 gm every eight hours for thirteen days. Repeated urinalyses, blood counts and electrocardiograms were performed to detect any evidence of toxic reactions to the drugs. The medications were given simultaneously. Fluids were forced during the acute relapse, ferrous sulfate was prescribed when any significant anemia was detected on admission, and the patients were restricted to no greater activity than a short walk to the dining hall or bathroom. Follow-up examination was identical to that described for patients treated with chloroquine.

## RESULTS

Eighty-nine patients were followed for a period of six to twelve months, and the remainder for one to six months. Striking differences between the results of the two treatments were noted and are discussed separately. Because a veteran may receive greater compensation if a greater relapse rate is indicated, the relapses were divided into proved or laboratory relapses and symptomatic relapses with negative smears.

Twenty-six patients received chloroquine therapy. Within three months 9 had experienced repeated symptoms of an acute relapse associated with a positive smear for *P. vivax*. One patient relapsed seven, and 1 nine months after completion of this course of therapy. Ten patients were subsequently treated with quinine and plasmochin. The eleventh, a physician, experienced repeated relapses every three to five months, with an increasing interval between relapses. An additional 11 patients complained of slight fever and other minor symptoms suggestive of relapse, but self-medication with quinacrine was taken and subsequent smears were negative. The total failure rate of 84 per cent and laboratory rate of 42 per cent were essentially the same as those obtained with quinacrine. No toxic symptoms from the use of chloroquine were noted. Its effect on the acute relapse was as prompt as that of quinacrine. It was more pleasant for the patient

\*Furnished through the courtesy of Mr. Shepherd M. Criss, Department of Medical Research, Winthrop Chemical Company, Inc. It is pointed out that the doses employed in this study differed from those given in the earlier reports on this drug in which tablets containing 0.30 gm. of the base were administered. Only tablets containing 0.15 gm. of the base (0.25 gm. of the diphosphate) are now available.

to take, since it neither produced gastrointestinal irritation nor discolored the skin. No definite relapses occurred during the five-week period of suppressive therapy, although 2 patients stated that they felt sick every Saturday, just before taking the weekly suppressive dose.

Sixty-three patients treated with the combined quinine and plasmochin regime were followed for six to twelve months after completion of therapy. No case of a laboratory relapse occurred. Sixteen patients stated that they had experienced symptoms, which they interpreted as an attack of malaria—a symptomatic relapse rate of 26 per cent. One of these had persistent splenomegaly, 6 were sub-

sequently admitted to the hospital for "malarial attacks," and negative smears were obtained. In some cases adequate cause for the fever was found in infection of the urinary or respiratory tracts, and the remainder were afebrile. No laboratory relapses occurred in an additional 40 patients followed for less than six months. All patients stated that they noted great improvement in their sense of well-being.

The toxic manifestations of plasmochin were not serious or severe. The principal toxic symptoms or signs observed were mild to severe epigastric burning, abdominal cramps and diarrhea. These symptoms most commonly occurred during and after the fifth day of therapy. Abdominal pain was severe enough in 2 cases to necessitate discontinuance of the medication for several doses before the treatment could be continued to completion. There was no relation of the severity of the gastrointestinal symptoms to other manifestations of toxicity. X-ray

studies in several cases during this period of discomfort failed to reveal any gastric hyperperistalsis or intestinal spasm.

Circulatory signs and symptoms consisted of the appearance or disappearance of ventricular extrasystoles concurrently with the administration of the drug in 1 case. Cyanosis was rarely observed, as was the central-nervous-system symptom of "nervousness." No evidence of any hemolytic anemia was encountered.<sup>6</sup> It should be emphasized, however, that only white patients were treated and that they were kept on restricted activity.

The usual symptoms of quinine toxicity—namely, tinnitus, fullness in the head and ears and headache—were noted in minor degree and caused no interruption of therapy. One patient who gave a history of hypersensitivity to quinine was uneventfully treated with chloroquine.

### Discussion

Our experience indicates that chloroquine is easier to administer to the patient and does not have the yellow-dye discoloration effect of quinacrine. Clinically, it was no more effective in preventing relapses than quinacrine. The combined quinine and plasmochin regime has proved as effective in reducing the relapse rate over a prolonged follow-up period as Most et al.<sup>1</sup> found it to be. It is expensive and takes time, and yet is effective in returning the non-working patient to gainful employment. Under controlled observation no toxic manifestations of importance occurred. The abdominal cramps seemed to be relieved best by rest. Sedatives and antispasmodics were ineffective. We do not recommend the combination except under controlled observation and restricted activity.

It is interesting that all the patients with the proved cases of recurrent malaria admitted to the hospital, with 2 exceptions, came from the Pacific area—New Guinea and adjacent islands, the Solomons, Netherlands East Indies, Philippine Islands and Okinawa. The exceptions had been stationed in the China and India-Burma theaters. No patients from the Mediterranean or Caribbean theater were encountered. This is of diagnostic importance, since many patients from the latter theaters have been referred to the hospital with the erroneous diagnosis of malaria.

We continue to see patients who were last in a malarial zone a year and a half ago, entering with their primary delayed malarial attack. Many had lacked their usual sense of well-being since they returned from overseas and may have experienced slight attacks in the interim. Almost without exception these cases have not been recognized as malaria by physicians, and the patients were admitted to the hospital with diagnoses of fever of unknown origin or pneumonia. No cause for the lighting up of these dormant infections was elicited.

FIGURE 1 Monthly Admission Rate, Averaged Quarterly, of Patients with Proved Vivax Malaria (September, 1945, to July, 1947)

Conversely, the prophesied subsidence of the malarial attacks of Pacific origin after three or four years has been borne out by the admission rate. Figure 1 illustrates the monthly admission for proved malaria, averaged quarterly. The curve suggests a possible effect of the combined quinine and plasmoquin therapy on the recurrence rate, since prior to July 1, 1946, many patients had been hospitalized two or more times, the admission rate thus being elevated. In addition, the patients admitted during the past six months had acquired the infection in 1944 or later. Certainly the bulk of those who contracted the disease in 1942 or 1943 are no longer experiencing symptoms that can be proved to be due to malaria.

### SUMMARY

Chloroquine (SN 7618) was as effective and better tolerated than quinacrine (atabrine) in acute

malarial relapses or when used for suppressive therapy. It does not further reduce the relapse rate of malaria of Pacific origin.

The combined quinine and plasmoquin regime, under controlled observation and restricted activity, affords a safe and effective means of markedly reducing the relapse rate.

## EXFOLIATIVE DERMATITIS DUE TO CODEINE\*

CAPTAIN JOHN H. MOYER, JR., M.C., A.U.S.†

WORCESTER, MASSACHUSETTS

CODEINE has been in use as a narcotic since 1832,<sup>1</sup> when it was first extracted from opium. Chemically, it is the methyl ester of morphine<sup>2</sup> containing a phenanthrene nucleus.<sup>3</sup> Today it is used in massive amounts, especially in sanatoriums, and yet drug eruptions due to sensitivity to this agent are extremely rare. Seidmann<sup>4</sup> stated that up to 1943 only 10 such cases had been reported in the literature. Since then at least 2 additional cases have been reported. The following case is presented because of the severity of both the skin and systemic manifestations.

### CASE REPORT

A 34-year-old man was admitted to the hospital with a diagnosis of scarlet fever. The past medical history revealed that the patient had had the usual childhood diseases a recurrent otitis media of a chronic nature and gonorrhea three times in the past 10 years. There was no allergic history. The family history was uncontributory. Six weeks before admission the patient had first developed a severe myositis of the shoulder, involving chiefly the trapezius muscle, for which he had received large daily doses of codeine, phenobarbital, salicylates and thiamine until the day of admission. About 7 days before entry he developed a mild generalized erythematous rash with a superimposed urticaria which caused a great deal of itching. This was unassociated with fever, sore throat or photophobia and subsided after 2 days. The erythema and urticaria recurred, however, 4 days later in a severer form and was associated with fever. The systemic review was essentially negative.

Physical examination revealed a well developed well nourished man. There was a generalized macular erythematous rash with numerous superimposed giant urticarial wheals from 2 to 8 cm. in diameter distributed over the entire body.

\*From the Belmont Hospital.

†Chief, Medical Chest Section, Brooke General Hospital, Ft. Sam Houston, Texas.

Over the bridge of the nose and malar prominences there was a small punctate papulopustular rash which was apparently quite recent in origin. Examination of the ears revealed a perforated right drum. Otherwise the physical examination was negative.

The temperature was 104°F.

The patient was taken off all medication and treated symptomatically. He continued to run a septic type of fever for approximately 4 days, after which the temperature suddenly dropped to low grade levels. By the 2nd hospital day the punctate pustular rash previously noted over the nose and malar prominences had spread to involve the entire face and upper portion of the chest but advanced no farther. On the 3rd hospital day the urticaria subsided leaving large purpuric spots on the involved portions of the skin. Numerous small desquamating areas were also noted at that time on the lower arms and legs. Soon thereafter a generalized desquamation of flaky loose scales up to several centimeters in diameter developed. The patient also complained of marked diplopia and eyeball pain which however subsided after 3 days without residual symptoms and without recurrence. It was noted that the patient was extremely sensitive to temperature changes such as a very mild draft or change of bedclothes during which he developed a frank chill. There was a marked tremor of the extended hands as well as an intention tremor which also subsided as the patient improved. On the 8th hospital day the corium layer of the hands and soles of the feet was shed in glove-like fashion similar to that seen in scarlet fever. The desquamating areas began to weep considerable amounts of serous fluid. This was followed by crusting and continued desquamation. About the 12th hospital day a secondary skin infection involving the antecubital fossa and legs developed. This was followed by a marked rise in temperature up to 104°F., with leukocytosis and marked regional lymphadenitis. The patient was placed on penicillin therapy (40,000 units every 3 hours) intramuscularly and tyrothricin locally to involved areas after which the temperature dropped to normal limits within 5 days. Symptomatic therapy and penicillin prophylactically were continued. His condition gradually improved during the next month although a great deal of desquamation was noted.

After convalescence it was thought advisable to determine the origin of the dermatitis. Patch tests with codeine pheno-

barbital, thiamine and sodium salicylate, both solution (1:1,000) and the powdered form of the drug being used, were performed. There was no reaction to these tests. The patient was then given intradermal injections of 1:10,000 of the same preparations at 1-week intervals. There was no reaction to salicylates, phenobarbital or thiamine. However, 30 seconds after the injection of codeine a giant urticaria at the site of injection about the size of the palm of the hand, as well as a generalized urticaria, developed. This subsided after eight hours. However, by the next morning there was a marked purpuric spot in the area of the skin test, as well as a fine punctate pustular rash involving the face similar to that observed on admission. At that time considerable concern was caused by the fear that a recurrence of the dermatitis had been precipitated. However, the rash entirely subsided within 48 hours without further complications. The patient was discharged on the 70th hospital day.

Repeated urinalyses during hospitalization were negative, with specific gravities ranging up to 1.028. Because of the diplopia a spinal tap was done, which was also negative, as were repeated blood cultures. Agglutination studies for typhoid, salmonella and the brucella organisms were also negative. Routine blood studies revealed a red-cell count varying from 4,500,000 to 5,000,000 during hospitalization. The white-cell count on admission was 8200 with 3 per cent eosinophils, 11 per cent lymphocytes, 2 per cent monocytes and 84 per cent neutrophils. By the 14th hospital day, during the height of the secondary infection, the white-cell count rose to 19,000 with 11 per cent eosinophils, 15 per cent lymphocytes, 6 per cent monocytes and 68 per cent neutrophils. On the 30th hospital day the white-cell count returned to normal, showing only 1 per cent eosinophils. On the day of discharge the white-cell count and differential were normal. The serologic findings were negative. Throat cultures revealed *Staphylococcus albus*. Cultures of the secondarily infected areas were positive for hemolytic staphylococcus. Repeated x-ray films of the chest were normal.

### DISCUSSION

Pollak<sup>4</sup> first described a case of pinhead-sized papulopustular eruption due to codeine in a one-and-a-half-year-old child who had been receiving codeine for some time in a cough mixture. This was similar to the presenting facial rash in the case reported above, except that in the former case the rash was mild and quickly disappeared after withdrawal of the drug without further complications.

An itchy erythematous rash due to codeine that was similar to the urticarial erythematous rash on the trunk and limbs in this case and that later cleared after mild desquamation was described by Von Essen<sup>5</sup> in a thirty-one-year-old woman.

The most frequent finding in reported cases has been an erythematous scarlatiniform eruption, which the case reported above also exhibited.<sup>1-12</sup> This manifestation was very well described and discussed by Scheer and Keil,<sup>6</sup> who reported such a case. In their patient the patch test was positive to a solution of codeine but was negative when the powder was used. Palmer's<sup>3</sup> patient also had positive patch tests to 1:100 and 1:1000 solutions.

Although patch testing is rarely of value in dermatitis medicamentosa, it was thought justifiable to attempt to determine the etiology of this patient's dermatitis in view of successful reports.<sup>3, 6</sup> However, patch tests employing both the powdered drugs and the 1:1000 solutions were negative. Intradermal skin tests using 1:10,000 solutions were then employed. These were negative for thiamine, sodium

salicylate and phenobarbital, but there was a marked reaction to codeine. Scheer and Keil first noted that codeine injected intradermally gave a positive wheal in normal persons and that the intradermal test was valueless. We were not aware of this at the time we attempted to determine the etiology of this patient's difficulty. Although no deaths have been reported from codeine sensitivity, there seems little doubt that poor judgment was exercised in the use of intradermal skin tests in this case, since it is easy to imagine that a severe recurrence of the exfoliative dermatitis may have been precipitated by this procedure. However, the diagnosis seems well established in view of the recurrence, after the intradermal injection of codeine, of a generalized urticaria followed by a punctate papulopustular eruption of the face similar to the original eruption.

None of the previously reported cases have run such a toxic course, nor have the patients had so many and severe skin manifestations as this patient presented. These included pustular papules, erythema, urticaria, purpura and eventually generalized exfoliative dermatitis. The patient was desperately ill for approximately a month, and only by the use of antibiotics for the control of secondary infections and by considerable nursing care was he saved. The marked transient eosinophilia has been observed previously in this condition,<sup>1, 9</sup> but as noted above is not a common finding in drug eruptions.

### SUMMARY

A case of exfoliative dermatitis due to codeine is reported. The rash was manifested by a papulopustular eruption of the face and generalized macular erythematous rash with superimposed urticaria, which was followed by weeping in some areas and generalized desquamation. For forty days the patient ran a severe course complicated by secondary infection. After recovery a skin patch test was negative but the intradermal injection of a 1:10,000 solution of codeine caused a generalized urticaria and mild manifestations of the original picture. This was thought to be sufficient evidence to establish the etiology.

## MEDICAL PROGRESS

## DIABETES (Concluded)

ELLIOTT P JOSLIN, M.D.\*

WITH THE CO-OPERATION OF LEO P KRALL, M.D.,† C C BAILEY, M.D.,‡ HOWARD F ROOT, M.D.,§  
PRISCILLA WHITE, M.D.,¶ AND ALEXANDER MARBLE, M.D. ||

## BOSTON

## PREGNANCY IN DIABETES

Pregnancy in diabetes continues to interest Dr Priscilla White,<sup>22</sup> and in an article presented before the Third Congress of Obstetrics and Gynecology, her conclusions were brought up to date

The typical course of a diabetic pregnancy as seen in diabetic clinics is the following one from conception to term the pregnancy has a 50 per cent chance for survival and terminating in a live birth. If pregnancies of diabetics are studied from viability on the chances for success increase to 65 rarely to 75 per cent. (The expected fetal survival at present is better than 90 per cent)

## The importance of vascular disease is stressed

Although fetal survival is possible with advanced arteriosclerosis, a review of our patients who had unexpected failures showed that when arteriosclerosis was so advanced that the arteries of the pelvis were calcified (30 cases), the chances for fetal survival were poor, 10 per cent. In 16 cases where every form of treatment we know was included, the survival rate to 19 per cent. Calcified pelvic vessels not revealed in the pre- or early pregnancy screening plates have been revealed in from 6 to 12 months after failures or stormy pregnancies. Intimal disease favoring occlusion — characteristic of diabetes — is inferred to be present before the calcium is deposited.

Seventy five per cent of our patients are delivered by Cesarean section, performed under spinal anaesthesia without preliminary sedation. Spontaneous normal deliveries are also conducted under spinal anaesthesia and with minimal sedation

For details of treatment of both mother and child, the original article must be consulted, but the following is a brief summary

The management of diabetes includes the prescription of diets high in carbohydrate 180 to 250 grams, high in protein 20 grams per kilogram of body weight, and fat to complete the caloric prescription of 30 calories per kilogram

Multiple doses of insulin protect the patient from the ketosis consequent to the low renal threshold for glucose and avoid hypoglycemia

§Associate in medicine, Harvard Medical School; physician-in-chief, New England Deaconess Hospital.

¶Instructor in pediatrics, Tufts College Medical School; physician, New England Deaconess Hospital; physician, Faulkner Hospital; consultant, Boston Dispensary.

||Instructor in medicine, Harvard Medical School; physician, New England Deaconess Hospital.

The treatment of the disturbed chemistry includes the use of ammonium chloride in doses of 4 to 8 grams daily acid ash, high protein diets. Sodium is restricted. The most important part of the treatment is the substitutional hormonal therapy.

Various routes of administration, types of therapy, durations of treatment have been employed but the best results in my experience have been with early and continuous stilboestrol and proluton intramuscularly. The present form of treatment is as follows:

Week of Pregnancy	Stilboestrol mg daily	Proluton mg daily
Up to 20th	5	5
20-24	10	10
24-28	15	15
28-32	25	25
32-38	50	50

Regulation of stilboestrol is controlled by serum levels of chorionic gonadotropin and proluton by urinary determinations of pregnandiol.

## METABOLISM OF CARBOHYDRATE AND FAT

An excellent summary of the work of the Coris and their associates at Washington University, St. Louis, was given by C F Cori<sup>23</sup> in his Harvey Lecture. It will be recalled that from these studies it became apparent that at least one site of action of insulin in the body is at the point at which glucose is admitted to the metabolic system by conversion to glucose-6-phosphate. This conversion of glucose takes place by reaction with adenosine triphosphate under the influence of a sulphhydryl enzyme, hexokinase. The Coris found that the hexokinase reaction was inhibited by anterior pituitary extract and that insulin opposed this inhibition. Insulin had no direct effect upon the reaction. Although not all the known facts can be fitted easily into the proposed scheme, a convincing demonstration of one site of action of insulin is now available. Stetten<sup>24</sup> regards Cori's work as of great significance and emphasizes the fact that once glucose has been phosphorylated, many pathways are open to it: it may be converted to glycogen or to fat, or it may be oxidized. Stetten and his co-workers<sup>25</sup> showed that in the well nourished rat, only about 3 per cent of the glucose ingested is converted to glycogen, whereas about 30 per cent (ten times as much) is consumed in the manufacture of fatty acids. More and more it is coming to be recognized that the metabolism of carbohydrate, protein and fat is not independent but that all three contribute to a common

metabolic pool to which active fragments are constantly being added and withdrawn. Investigation along this line is for the first time possible through the use of isotopes by means of which individual molecules can be labeled and traced through the body.

#### DIABETES SECTION OF THE UNITED STATES PUBLIC HEALTH SERVICE

The Diabetes Section of the United States Public Health Service was formed in recognition of the increasing public-health aspects of diabetes. There is a growing diabetic population, and indications are that only about half the patients have been found. To avoid complications of the disease, efforts must be made to find the others early and to start their education. The objectives of the Diabetes Section are to demonstrate the application of public-health measures in the early detection of the disease and to stimulate, encourage and support research in all aspects of diabetes, including the development of new laboratory methods and techniques.

Among the accomplishments of this section have been the Oxford Diabetes Survey cited above and two diabetes units. One is established in co-operation with the Florida State, Duval County and City of Jacksonville Health Departments. The second unit works in co-operation with the Commonwealth of Massachusetts and the Town of Brookline Health Departments. The project includes early detection of cases and dissemination of information about diabetes to the diabetic patient and to the public. Patients with newly discovered diabetes are referred to their family physicians for further study and treatment.

A new rapid screening test for blood sugar—described below—has been devised. Exhibits on diabetes have been presented at meetings of the American Public Health Association and sectional medical meetings and in co-operation with the American Diabetes Association at the annual meeting of the American Medical Association in 1947. Educational material is being prepared for general-population groups, health departments and the practicing physician in co-operation with the American Diabetes Association.

#### NEW RAPID BLOOD SUGAR TESTS

The Benedict test affords a simple and convenient method by which not only physicians but also diabetic patients may test the urine for sugar. Modifications such as the "Clinitest" and "Galatest" allow for even greater speed and convenience. It would be of tremendous advantage to all concerned if simple and quick methods were available also for the determination of the blood sugar. Some progress in this direction has recently been made. Hagedorn and his collaborators<sup>36</sup> have devised rapid modifications of their ferricyanide method, including a procedure in which most of the reagents are provided

in tablet form. A bedside method for the rapid determination of the approximate sugar content of the blood has been worked out by Leech and Woodford.<sup>37</sup> In this procedure, which requires a minimum of equipment and laboratory experience, blood proteins are precipitated by means of zinc hydroxide and the concentration of sugar in the filtrate determined by use of Sumner's dinitrosalicylate reagent. By either of these methods a blood sugar determination may be made within five minutes of the time of collection of the blood.

The third new method, developed by the Diabetes Office of the United States Public Health Service,<sup>38</sup> is particularly suited for rapid, large-scale screening tests in surveys and other studies of large population groups. The procedure is based on that of Hagedorn, but all reagents are in tablet form and the steps requiring experience in chemical techniques and all fluid reagents have been eliminated. Within five minutes a sample of blood (0.1 cc) can be classified as having above or below a certain glucose concentration.

With these new tests public-health departments have available means of early case finding, and the practicing physician can be materially aided in the better care of his diabetic patients.

#### ALLOXAN DIABETES

In previous years, attempts have been made to include in the progress reports<sup>39</sup> all references that have appeared on the subject of alloxan diabetes. The present article attempts to include all published reports on this subject since the previous summary in April, 1946. The subject has been extensively reviewed elsewhere.<sup>40-43</sup>

#### Chemistry

The chemistry of alloxan has been reviewed by Chen.<sup>44</sup> The diabetogenic action continues to be limited to alloxan and a few very closely related chemicals that may well change into alloxan once they are introduced into the body.

Brückmann and Wertheimer<sup>45</sup> report that *n*-methyl, ethyl and propyl alloxans, as well as alloxantin, dimethyl alloxantin, diethyl alloxan, dialuric acid and methyl dialuric acid, produce diabetes when injected into rabbits. Others<sup>46-48</sup> have shown that various ones of these compounds are diabetogenic, and Hidy<sup>46</sup> has stressed the fact that the intact pyrimidine ring is essential for the diabetogenic activity of any chemical compound such as alloxan.

Tipson and Ruben<sup>49</sup> claim that alloxan or its reduction product is present in the liver of normal animals and also describe their "purple" test for alloxan.<sup>50</sup> Karrer et al.<sup>51</sup> report a very sensitive test for the detection of alloxan and claim that this method will detect 0.5  $\gamma$  of alloxan per cubic centimeter of aqueous solution. Using this method, however, they were unable to detect any alloxan in the serum or urine of diabetic patients.

The experiments of Iyengar<sup>42</sup> suggest that alloxan experimentally acts as an activator for insulin

### Physiology

In addition to the rabbit, rat, dog, monkey, pigeon and turtle, diabetes has been produced with alloxan in sheep,<sup>43, 44</sup> hamsters<sup>45</sup> and cats.<sup>46</sup>

Shipley and Rannefeld<sup>47</sup> showed that the injection of small subdiabetogenic doses of alloxan could irreversibly alter the functional reserve of the islet-cell tissue, as demonstrated by the glucose-tolerance test. Animals so treated if then given anterior pituitary extract developed a markedly increased blood sugar.

With ordinary diabetogenic doses of alloxan there is complete functional recovery from initial kidney damage.<sup>48</sup> Duffy<sup>49</sup> found that the dose of 200 mg. of alloxan per kilogram of body weight intravenously in rabbits resulted in death in many of the animals. Some of those that survived, however, developed diabetic cataracts.

Lazarow and Palay<sup>40</sup> found the intravenous injection of 40 mg. of alloxan per kilogram of body weight in rats a satisfactory method of producing diabetes mellitus. The intraperitoneal route required larger doses.

The withdrawal of all foods from adult rats for a period of forty-eight to sixty hours before the injection of alloxan renders the animals more susceptible than the nonfasted animals to the diabetogenic action of alloxan.<sup>41</sup> According to Houssay and Martinez,<sup>50</sup> a low-protein or high-lard diet increases the rat's susceptibility to alloxan. The high-lard diet, however, loses its effects if methionine, thionin or coconut oil is added.

Levey and Suter<sup>51</sup> claim that the administration of ascorbic acid to rats increases the diabetogenic action of low doses of alloxan if the vitamin is given within one minute before the administration of alloxan. It has been stated that ketosis has been produced in alloxan-diabetic rats by means of a diet high in niacin.<sup>44</sup>

The initial hyperglycemia followed by temporary hypoglycemia that follows the injection of alloxan and precedes the onset of true diabetes has been discussed again.<sup>45</sup> Goldner and Gomori<sup>46</sup> present further evidence to support the hypothesis that the secondary hypoglycemia following the injection of alloxan is pancreatic in origin.

Canzanelli<sup>47</sup> found that, *in vitro*, alloxan has no direct effect upon liver glycogenolysis, and these findings therefore oppose the concept that the initial hypoglycemia of alloxan diabetes is a result of an effect of alloxan on the liver. It has been shown that alloxan inhibits muscle glycolysis and that this inhibition can be reversed by the addition of cysteine.<sup>48</sup>

The glycogen reserve of the muscles and of the liver in alloxan-diabetic rats has been approximately doubled by the administration of insulin.<sup>49</sup> Weber<sup>52</sup>

found that the glycogen content of the liver after twenty-four hours of fasting was higher in alloxan-diabetic rats than in normal rats, whereas the glycogen content of the muscles was lower.

Franks et al.<sup>71, 72</sup> believe that the rise in the plasma inorganic phosphates of alloxan-diabetic rats during diabetic coma is due to a breakdown of the liver organic phosphates associated with a deficiency of insulin. The acid and alkaline phosphatase activity is significantly increased after the development of alloxan diabetes in rats according to Drabkin and Marsb,<sup>73</sup> and the administration of insulin produces a decrease in the activity of both acid and alkaline enzymes.<sup>74</sup>

Dogs made diabetic with alloxan have a more severe diabetes and require much higher doses of insulin than dogs made diabetic by pancreatectomy, according to Thorogood and Zimmerman.<sup>75</sup> Although some believe that this results from decreased food absorption since the digestive enzymes are decreased in amounts, these workers postulate the possibility of a second hormone from the pancreas, the absence of which allows the diabetes to become more severe and predisposed to ketosis.

Foglia et al.<sup>76</sup> showed that depancreatized rats that later receive a diabetogenic dose of alloxan develop after the administration of glucose a hyperglycemia, which is more acute and of longer duration than when rats that have been depancreatized alone are given glucose.

The secondary transitory hyperglycemia that follows the injection of alloxan into dogs is markedly delayed in dogs in which a vagotomy-thoracotomy operation has been performed, according to Shipley and Beyer.<sup>77</sup>

Kendall and his associates<sup>78</sup> report a transitory period of hypercholesterolemia and hyperlipemia during the early stages of severe diabetes in rabbits injected with alloxan.

In 20 of 30 rabbits injected with alloxan by Herbut et al.<sup>79</sup> a very severe periportal necrosis of the liver occurred. The feeding of reduced iron to 2 diabetic and 2 controlled rabbits for two and a half weeks resulted in the deposition of iron in the liver and other organs. Attempts are being made to produce hemochromatosis by this method.

Rabbits made diabetic with alloxan that become pregnant have abortions, or premature delivery in half the experiments.<sup>80</sup> No evidence of an increased birth weight among the fetuses in diabetic rabbits was found, however. In rats made diabetic with alloxan, the pregnancies reach full term and result in the birth of healthy fetuses with normal birth weights. Injection of alloxan into pregnant animals appears to have no ill effect on the fetuses.

### Prevention

Soon after it was proved that alloxan could produce diabetes in animals attempts were made to find substances that would prevent its diabetogenic

action This was quite logical, for if alloxan had anything to do with the etiology of diabetes in human beings it would be quite important to find some substance that would prevent its action It has been known for a long time that alloxan has an especial affinity for the sulfhydryl group, and Lazarow<sup>81</sup> has shown that, if large doses of glutathione or cysteine are intravenously injected into rats immediately before the injection of a diabetogenic dose of alloxan, diabetes is prevented If, on the other hand, these substances are given one minute after the injection of alloxan only partial protection results If the injection is made three or four minutes after the injection of alloxan no protection is seen<sup>82</sup> Recently, it has been shown that BAL (British Anti-Lewisite) also prevents the diabetogenic action of alloxan in rats,<sup>83-85</sup> presumably because it too is a sulfhydryl compound

Banerjee<sup>86</sup> found that 100 mg of nicotinic acid per kilogram of body weight injected intravenously and followed by a like dose of alloxan protected 5 rabbits from diabetes When doses of 200 mg per kilogram were used, however, 2 of 3 rabbits developed diabetes

Clamping the kidney vessels in the dog before the injection of alloxan prevents the development of diabetes according to the report of Jimenez-Diaz et al<sup>87</sup> Other workers found that clamping the renal pedicle of rabbits or rats did not prevent the diabetogenic action of alloxan or the histologic changes in the islets of Langerhans<sup>88-90</sup>

Walpole and Innes<sup>91</sup> found that ligation of the main pancreatic duct in rabbits prevents the action of alloxan, but no other reports supporting or rebutting this finding have yet appeared

It has previously been reported that the injection of adrenalin intraperitoneally before the injection of alloxan prevented diabetes<sup>92</sup> LeCompte and Bailey<sup>89</sup> found that the injection of small quantities of epinephrine intraperitoneally into rats produced a marked constriction of the capillary and small blood vessels of the intact pancreas, which could be seen microscopically It is presumably the vasoconstriction that keeps the alloxan from reaching the islets of Langerhans and prevents the diabetes

It has been suggested that pentnucleotides act as an antagonist to alloxan in the rat<sup>93</sup>

### *Influence of Endocrine Glands*

Gaarenstroom et al<sup>94-96</sup> report that extirpation of the hypophysis in animals already made diabetic with alloxan leads to a marked decrease or even total disappearance of glycosuria and a fall in the blood sugar, in fasting animals After administration of sugar, the blood sugar rises again to high levels

Bailey and his co-workers<sup>97</sup> showed that if rats were hypophysectomized and then given alloxan, diabetes developed but was much milder than that in control animals given alloxan alone

Houssay and his associates<sup>98</sup> have studied the relation of the thyroid gland to alloxan diabetes quite extensively They report that thyroidectomized rats show a greater resistance to the diabetogenic and toxic action of alloxan than control animals and that thiouracil-treated rats show even greater resistance to alloxan

Experimental hyperthyroidism produced by the administration of thyroid extract increases and thyroidectomy decreases the sensitivity of rats to the action of alloxan<sup>99</sup> Dogs with transitory diabetes as a result of the injection of alloxan develop permanent diabetes when they are treated with thyroid extract,<sup>100</sup> but the administration of thyroid extract does not produce diabetes unless the islets of Langerhans have previously been injured A very unusual finding was that thyroid treatment of pancreatectomized rats in which diabetes had already become incipient caused its complete disappearance In spite of continued treatment, however, diabetes reappeared in a third of the animals The nontreated controls all eventually became diabetic<sup>101</sup>

Suarez Soto<sup>102</sup> also produced so-called "meta-thyroid diabetes" by administering thyroid extract to dogs whose pancreases had been handicapped by the administration of small doses of alloxan

No amelioration of alloxan diabetes was found when rats were treated with diethyl stilbestrol<sup>103</sup>

Janes and Friedgood<sup>104</sup> reported that when alloxan-diabetic rats were adrenalectomized a marked reduction or complete disappearance of diabetic symptoms resulted On further study of this problem, however, they found that the amelioration of the diabetes following an adrenalectomy was associated with a lowered food intake rather than the direct results of the adrenalectomy<sup>105</sup>

### *Pathology*

The pathology of alloxan diabetes has been described in a most complete article by Duff<sup>106</sup> Two new findings have been reported in the last year Duff et al<sup>107</sup> observed moderate to extreme hydropic degeneration of the pancreatic ductules and islets of rabbits made diabetic with alloxan after several months of diabetes Such changes were detected as early as forty-five days and were never absent after ninety days, provided the average fasting blood sugar level was 303 mg per 100 cc or higher These hydropic degenerative changes, both in the ductules and in the islets, are reversible if the diabetic state is treated with insulin

Proliferative changes have been described by Di Pietro<sup>108</sup> in the centroacinar cells of the pancreas and the intracanalicular ducts

Grossman and Ivy<sup>109</sup> believe that the vacuolization of the intralobular duct cells of the pancreas, along with their finding of decreased responsiveness to secretin, suggests that the small duct cells participate in the formation of pancreatic juice

### Clinical Considerations

The clinical implications of alloxan diabetes have been summarized by Bailey and LeCompte,<sup>110</sup> and the relation between experimental and human diabetes has been compared by Gale.<sup>111</sup> It has been pointed out that alloxan is a chemical with dangerous toxicity and its use in man at present is ill advised.

Since alloxan destroys the islets of Langerhans it was quite natural that it has been used in the treatment of hyperinsulinism. Talbot and Bailey<sup>112</sup> administered alloxan to an eight-month-old baby with the clinical and laboratory findings of hyperinsulinism, with somewhat encouraging results. This was done only after careful surgical exploration had failed to reveal any evidence of a pancreatic adenoma. The authors warn of the extreme dangers in the use of this drug.

The danger associated with the administration of alloxan in human beings has been well illustrated in a case of islet-cell carcinoma with extensive metastasis in which alloxan had been used as a last resort.<sup>113</sup> After three injections of alloxan the patient developed acute yellow atrophy and died with extensive liver necrosis.

Conn<sup>114</sup> reports that alloxan may destroy the normal islets of Langerhans in the pancreas. In the treatment of a case of hyperinsulinism with alloxan, no effects were noted on the pancreatic islet-cell adenomas, but the normal islet cells were damaged and the patient developed diabetes after the islet-cell carcinoma had been removed surgically. A biopsy of the pancreas in this case confirmed islet-cell damage.

Another case of islet-cell carcinoma of the pancreas with liver metastasis was treated with alloxan by Flinn et al.,<sup>115</sup> but no clinical effect from the alloxan was observed.

Uric acid diabetes is reported by Griffiths<sup>116</sup> of the Australian Institute of Anatomy, Canberra, Australia, as having been produced experimentally in rabbits. Recognizing that diabetogenic doses of alloxan, as well as minhydrin (though nondiabetogenic) lower blood reduced glutathione levels in rats appreciably, he administered uric acid parenterally with the thought that it might exert a diabetogenic action under such conditions. Intra-peritoneal injections of 1 gm of uric acid per kilogram of body weight into these deficient animals caused an initial hyperglycemia lasting about eight hours. Later, despite food, the animals remained hyperglycemic, and glycosuria persisted for the next four or five days. The blood sugar response resembled that which follows an injection of alloxan.

\* \* \*

The growth of interest in diabetes continues. Associations have been formed in the United States, England, France, Denmark, Belgium, Holland, New Zealand and Australia. In England and

France publications for the lay public are issued, appearing in three or four issues yearly. The American Diabetes Association inaugurated such a policy beginning with the issuance of the *ADA Forecast* in January, 1948. This blue-covered magazine has been designed with great care. It is especially to be commended because there are no advertisements. I am sorry not to feel at liberty to disclose the sponsors of the publications, who have had so much to do with making their timely appearance possible. *Diabetes Abstracts* and the *ADA Forecast* are certainly very forward steps in the dissemination of knowledge of diabetes for doctors, patients and the public and surely cannot but result in a notable advance in treatment.

### CASE 3414

#### PRESENTATION OF CASE

A seventy-one-year-old man was admitted to the hospital because of orthopnea and ankle edema.

Ten years before entry he was treated in the Out Patient Department for late syphilis. Because of his age he was given bismuth only, and the blood Hinton test became negative. An x-ray film of the chest showed an enlarged heart and a tortuous aorta, with calcification of the aortic knob. Six years before entry he began to have dyspnea on exertion, and physical examination revealed an enlarged heart, with a regular rhythm, a soft apical systolic murmur (Grade II) and a soft aortic diastolic murmur (Grade I). He was digitalized and took digitalis irregularly ever since. The blood pressure was 140 to 150 systolic, 60 diastolic, the pulse 75-85, and the serologic tests for syphilis had been persistently negative. During the two weeks prior to admission he had severe dyspnea, with orthopnea and dependent edema.

Physical examination revealed a slightly cyanotic and icteric man. The neck veins were distended. There were fine, scattered rales in both lungs. The heart was enlarged, with the apex in the sixth space in the anterior axillary line. There were an aortic systolic (Grade II) and a diastolic (Grade I) murmur. The liver was enlarged and tender, and there was pitting edema of the lower legs.

The temperature was 100°F (rectal), the pulse 100 (irregular), and the respirations 24. The blood pressure was 145 systolic, 60 diastolic.

The white-cell count was 9300, with 70 per cent neutrophils. The hemoglobin was 13.5 gm. A van den Berg reaction was 0.9 mg per 100 cc direct, and 4.2 mg indirect (later 0.9 mg direct and 2.1 mg indirect). A cephalin-flocculation test was negative (later, +++ in forty-eight hours). The non-protein nitrogen, total protein and prothrombin time were within normal limits. Routine urine and stool examinations were negative.

An electrocardiogram showed auricular fibrillation and ventricular complexes arising from many different ectopic foci. A chest film demonstrated an

enlarged heart of aortic configuration, with calcification in the aortic arch, and congestive changes in both lungs.

The patient was treated with digitalis, ammonium chloride, mercurhydride and a low-sodium diet. Later, in view of the electrocardiographic findings, the digitalis was discontinued, and he was carried on 0.2 gm of quinidine daily. A good diuresis was obtained, and the pulse steadied to 70 to 80 per minute. However, he began to have anorexia, nausea and right-upper-quadrant tenderness attributed to distention of the liver capsule. One week after admission he suddenly developed pain in the right upper arm, which became cold, blue and pulseless. He was given spasmalgin and prepared for immediate embolectomy. However, in the interval the embolus passed farther down the arm, and operation was postponed. He was put on dicumarol and heparin, and the arm finally regained its normal circulation. The prothrombin time increased to 65 seconds (control 17 to 18 seconds), and the clotting time to 32 minutes. Two weeks after admission he developed repeated vomiting, which subsided the next day. He was given digifolin (1 cat-unit intramuscularly every other day) as well as the quinidine. He continued to have abdominal discomfort of varying severity without localization or tenderness and with negative x-ray studies. Four weeks after admission he suddenly had pain in the upper part of the abdomen and lower portion of the chest, restlessness, cold, clammy, dusky skin and a slow, irregular, weak pulse. The blood pressure was 80 systolic, 60 diastolic. There were a few rales in both lung bases, and the abdominal peristalsis was normal on auscultation. An electrocardiogram showed a rate of 65, a PR interval of 0.22 second, marked widening of the QRS complexes (0.29 second) and high T waves. The white-cell count was 19,200. Two hours later two examiners noted absent abdominal peristalsis. Both dicumarol and quinidine were discontinued. By noon the patient was much improved, ate well and had two stools. On the following day the white-cell count was 9800, the nonprotein nitrogen 67 mg per 100 cc, and the prothrombin time 36 seconds. The urine was normal, and the stools gave a ++ guaiac reaction. A few days later an electrocardiogram showed a more normal rhythm and rate, and a less prolonged QRS complex (0.16 second). A stool was negative for guaiac. The patient was again given dicumarol, and the epigastric distress returned, especially after the ingestion of food. He developed rapid fibrillation, with an apex rate of 120 per minute. He was given purodigin, and the pulse rate diminished to 84, and the pain subsided. He died a few hours later, one month after admission.

#### DIFFERENTIAL DIAGNOSIS

DR. WYMAN RICHARDSON: I always wonder how the experts grade murmurs, and, also, I always suspect that a soft murmur means a faint one, and a

harsh murmur, a loud one, but I am not sure of all this

I call attention to the fact that about three quarters of the bilirubin in this case was protein bound. I have called attention many times at these conferences to the fact that indirect bilirubin by the van den Bergh method means the total amount, including both that which requires the addition of alcohol and that which needs no addition of alcohol. Is that correct, Dr. Mallory?

DR. TRACY B. MALLORY: It must be.

DR. RICHARDSON: The direct test measures bilirubin that is not protein bound, and the indirect that which is due to protein-bound bilirubin. The finding in the case under discussion shows a slight increase of the blood bilirubin, most of which is due to protein-bound bilirubin. This is the significant point. One would expect to find some hemolytic process rather than an obstructive or intrahepatic process, although I do not think one can depend too much on this test.

The cephalin-flocculation test I am inclined to disregard, although probably I should not do so.

The nonprotein nitrogen at the time of entry was normal but later became elevated.

Digitalis was omitted — I suppose because of the ectopic beats and the suggestion of an irritable myocardium. Quinidine was given in small doses. It surprises me that, if the drug were used at all, more was not used. That amount may have been considered sufficient to prevent a sudden arrhythmia.

The clotting time may not be increased even though the prothrombin time is increased, but when the prothrombin time gets as high as that in the case under discussion, there is usually an increase in the clotting time too.

In the blood examination nothing is said about the distribution of the cells, and I have said much too much at these conferences about blood smears so that I will not say any more.

I think it is likely that the patient died of gastrointestinal hemorrhage. I want to say a few words about the use of anticoagulants. I am sure that I am a "stick-in-the-mud" regarding medicine and probably I am ultraconservative, but I should like to point out that when one uses anticoagulants and produces a prothrombin time of 65 and a clotting time of 32 minutes, one is adding a serious risk to the condition that the patient already has. I am not saying that anticoagulants should not be used when they are indicated. In some cases the calculated risk may be taken. But it seems to me that the pendulum has swung too far. I think it is fair to point out that a patient with a clotting time of 32 minutes is in constant danger of having a major vascular accident or major hemorrhage, as we know from our contact with hemophilic patients. There is a patient on the surgical wards now with a peculiar type of bleeding and a clotting time of 32 minutes,

and everyone is trying to bring that down. I do not want to go into the field of anticoagulants in phlebotrombosis, but I do think that we are going to find more and more cases in which increasing the prothrombin time has led to serious catastrophe or near catastrophe and in which the risk is not being clearly met. I am not doubting the integrity of those who use it and report on it, but it takes several years for the dangers to become apparent. Its use may have been justified in this case. This is the end of the sermon. I give it now, because I shall probably be wrong about this case and would not dare to talk about it afterwards.

What was this episode when the patient suddenly had upper abdominal pain? That is where the problem lies in this case. He became restless and had cold, clammy skin, a peculiar change in the electrocardiogram and an increased white-cell count. But in two hours he was very much better. What could have been the cause of this? My first and final thought was that he had a ruptured vessel, probably an artery. One might think of a pulmonary embolism. Why was it not a pulmonary embolism? It could have been, but it seemed to me to be rather a too rapid recovery. The white-cell count seemed to return to normal too rapidly. The same statement holds true for a ruptured viscus. If a viscus had ruptured into the abdominal cavity, I do not believe that the patient would have improved so much in two hours. The white-cell count of only 9800 may have represented a reaction to severe infection. I am unable to rule it out, but I doubt very much that it was infection. It may have been a hemorrhage into a closed cavity, such as rupture of an aneurysm, and that is a possibility that I cannot rule out. The thing that made me think of hemorrhage into the gastrointestinal tract was that he had had a great deal of abdominal pain, and something happened to intestinal peristalsis. I thought that loops of bowel might have been distended with blood. The nonprotein nitrogen rose to 67 mg per 100 cc, which did not seem explainable on the basis of shock because he did not appear to be in shock except for a very short period. One further explanation of the attack could be a coronary occlusion, with myocardial infarction. That is about all I can do except to say what the trouble was in the first place. He might have had a syphilitic aortitis. I think the evidence is against that because of the negative blood Hinton test. I assume that a Hinton test was done, although it is not mentioned that it was done in dilution and there may have been a so-called prezone phenomenon, if it were done in dilution, it would finally show up positive in the smaller dilutions.

DR. MALLORY: We know that the blood Hinton test was positive at one time and eventually became negative under treatment.

DR. RICHARDSON: I am taking the diagnosis of syphilis for granted. The problem is whether the

patient had syphilitic aortitis on admission, if so, the chances are that he would have shown a positive blood Hinton reaction. I do not believe that one can rule aortitis out, however.

He may have had subacute bacterial endocarditis. There seems to be little to suggest that disease other than the emboli. With this vascular setup he might, of course, have had periarthritis nodosa, which we frequently talk about at these conferences, I see nothing that points to it.

I have already mentioned the question of massive pulmonary embolism. He may have had that to start with, and the whole process may have been due to thrombosis of the pulmonary circuit. There does not seem to have been a cor pulmonale, the heart failure seems to have been more diffuse.

The sudden death, I suppose, may well have been a true cardiac death, and the whole thing cardiac from start to finish. I will postulate, however, that the underlying disease was arteriosclerotic—that the patient had a calcareous aortic valve, with coronary insufficiency, possibly associated with interference with the coronary intake at the coronary ostia, and that he had pulmonary infarction. I will explain the jaundice on the basis of the absorption of blood pigment from a fairly large infarction. I think he had, undoubtedly, auricular thrombi or, possibly, mural thrombi to account for the systemic circulatory embolism (unless one wants to believe that he had phlebothrombosis, with a very large, patent foramen ovale). Whether or not one has to consider intrinsic liver disease and whether one can explain the icterus on the basis of a congestive liver, I do not know, I suppose it is possible. At these conferences I am frequently given a case of liver disease to discuss, and this probably will turn out to be one. I am going to say, however, that this man had massive gastrointestinal hemorrhage, perhaps from an ulcer. He had calcareous aortic stenosis, coronary insufficiency, old pulmonary infarction, auricular thrombi and many other conditions.

A PHYSICIAN: Did the increase in clotting time occur after the administration of dicumarol or heparin?

DR RICHARDSON: I do not know. I assumed that the heparin was not continued. It was used for immediate effect until the dicumarol took hold. I assume that that could account for the increase in clotting time and not the heparin, but I do not surely know.

I forgot about the x-ray films. Perhaps we should see them now.

DR JAMES J. MCCORN: This is the chest film taken on admission. The left side of the heart is quite enlarged and probably represents an enlarged left ventricle. There is a plaque of sclerosis inside the aortic arch and a small amount of fluid in the costophrenic sinus. There is evidence of dilated vessels in the lung. This is the plain film of the abdomen, in which the liver does not appear to be

enlarged, there are no dilated loops of bowel. We have two films of the stomach, and they do not show evidence of ulcer.

DR RICHARDSON: I have no comment to make and no change in what I have said. I did not believe that there would be evidence of ulcer.

DR ALFRED KRAVES: Would Dr Richardson consider the possibility of coronary thrombosis superimposed on an old syphilitic aortitis to account for the embolism to one arm, in addition to the possibility of mesenteric embolism to account for the abdominal pain?

DR RICHARDSON: I agree. Very likely the emboli arose from a myocardial infarction. I thought of mesenteric arterial thrombosis, and I tried to say so but had too much language difficulty. However, I think that if the patient had had thrombosis of the mesenteric artery, he would not have been much better in two hours. On the contrary, he would have been much worse. Do you agree with that, Dr Cope?

DR OLIVER COPE: Yes, I think that is so.

DR RICHARDSON: Also, mesenteric thrombosis results in a very high white-cell count. I have seen it go up as high as 75,000 or 80,000.

#### CLINICAL DIAGNOSIS

Probable ventricular fibrillation

#### DR RICHARDSON'S DIAGNOSES

Calcareous aortic stenosis  
Coronary insufficiency  
Pulmonary infarction (old)  
Auricular thrombi  
Massive gastrointestinal hemorrhage (? ulcer)

#### ANATOMICAL DIAGNOSES

*Hypertrophy and dilatation of heart*  
Syphilitic heart disease, with aortic insufficiency, minimal  
Syphilitic aortitis, minimal, inactive  
Chronic passive congestion

#### PATHOLOGICAL DISCUSSION

DR MALLORY: Autopsy did not explain all the findings. The primary underlying disease was in the heart, which was very much hypertrophied, weighing 720 gm., all the cavities and all four valve rings were uniformly dilated, and there was enough separation of the cusps of the aortic valve to make us believe that there had been syphilitic involvement. Seventy years is a very advanced age in which to see syphilitic involvement of the aortic valve. Patients with such a lesion ordinarily die at least a decade earlier than that.

Microscopical sections from the aorta showed some degree of vascularization of the media but almost no lymphocytic infiltration, which I think is consistent with a totally burned-out syphilis. There was no blood in the intestinal tract at the time of

autopsy, and nothing to explain the earlier episode of melena, which may have been due to dicumarol as Dr Richardson suggested. The liver showed a moderate but not severe grade of passive congestion. There were no pulmonary infarcts. The coronary arteries were patent. The lungs were acutely congested and edematous, as in cases of acute heart failure.

One other interesting finding that we see very rarely at autopsy was marked dilatation of all the lacteals in the duodenum and jejunum with fat-containing chyle. There was also a considerable amount of fat residue in the stomach. In medico-legal cases in which death is instantaneous, it is not rare to see lacteals containing chyle. We see it here not more than once in several hundred autopsies, presumably because the digestive processes slow down and stop many hours before the patient dies. That is a physiologic phenomenon, however, with no pathologic significance.

There was one peculiar finding, which I cannot explain—a few small foci of active hematopoiesis in the liver and a few more in the spleen. The bone marrow showed disproportionate activity of the red-cell series but a total cellularity that was rather below normal than above. This suggests that the patient had a moderate degree of blood dyscrasia, which I am unable to diagnose. The spleen weighed only 190 gm, which is well within normal limits, and it is unlikely that this was a hemolytic anemia.

DR KRANES: Then no source was found for the embolus in the arm?

DR MALLORY: No.

DR RICHARDSON: According to you, the patient is still alive.

DR MALLORY: He had a markedly hypertrophied and dilated heart.

DR RICHARDSON: He probably died of ventricular fibrillation or something of that sort. Perhaps the quinidine dosage should have been increased, but perhaps those treating the patient were afraid to do so because of the embolus.

DR MALLORY: The degree of aortic-valve involvement was minimal. I do not believe that one could blame the cardiac hypertrophy and failure on aortic insufficiency.

### CASE 34142

#### PRESENTATION OF CASE

A seventy-six-year-old widow entered the hospital because of inability to swallow.

The patient had been in excellent general health until about six months before admission, when she had an episode of abrupt syncope following a fall, with two similar episodes in the next few months, there were, however, no convulsions, and rapid recovery of consciousness followed each episode. One month before admission she noticed the abrupt onset of dysphagia followed by the inability to

swallow anything but liquids. She reported the presence of a crampy, substernal pressure sensation, which was relieved by regurgitation of undigested food. In the week before entry the patient noticed some bright-red blood streaking in the regurgitated material, but there had been no previous bleeding. There was no radiation of pain and no abdominal or systemic symptoms. She had lost a great deal of weight in the three weeks before admission but did not know the exact amount. She denied chest pain,

FIGURE 1

dyspnea, hemoptysis, ankle swelling, jaundice, melena or changed bowel habits.

Physical examination revealed a well developed, poorly nourished woman with a moderate memory defect who was coughing frequently but was in no obvious distress. Examination of the chest and abdomen was negative.

The temperature was 99.6°F, the pulse 100, and the respirations 26. The blood pressure was 130 systolic, 75 diastolic.

Urinalysis revealed a + test for albumin and rare red cells and 10 white cells per high-power field in the sediment. The hemoglobin was 12.4 gm, and the white-cell count was 9000, with 86 per cent neutrophils. The serum protein was 5.7 gm per 100 cc, the chloride 104 mEq per liter, and the nonprotein nitrogen 22 mg per 100 cc. The sedimentation rate was 23 mm in one hour.

X-ray films of the chest revealed elevation of the right side of the diaphragm, with partial fixation and fluid in the right costophrenic angle. There were areas of haziness and mottled density throughout the entire right lung field, with an area suggesting infiltration in the first and second interspaces, the left lung field showed mottled areas of density. The left main bronchus was well seen, but the right was not visualized. A barium swallow demonstrated a smooth, fusiform narrowing in the esophagus for a distance of 5 cm just below the carina (Fig 1), but there was no evidence of shelf formation, destruction of the mucosa or ulceration. Passage of barium was delayed, but there was no true obstruction.

Bronchoscopy demonstrated a concentric constriction below the right middle-lobe orifice, but no biopsy was obtained. Esophagoscopy demonstrated an obstruction 19 cm from the upper gum, which appeared diffuse and granular. The biopsy was reported as showing chronic inflammation. Cytologic examination of the sputum was reported as doubtful.

During the period of study the patient deteriorated rapidly. She developed anxious, gasping respirations and duskeness of the nail beds, ears and nose. Laminograms of the right lower-lobe bronchus showed an apparent area of narrowing about 1 cm below the upper-lobe orifice. Later chest examination demonstrated dullness over the entire right side, with absent breath sounds over the upper third. Another examination of the sputum on the fourteenth day was negative for tubercle bacilli but positive for tumor cells. The patient went downhill progressively and died on the eighteenth hospital day.

#### DIFFERENTIAL DIAGNOSIS

Dr EDWARD D. CHURCHILL: Inasmuch as no statement is made to the contrary, I assume that there were no neurologic residua to the episodes of syncope. They sound like manifestations of cerebral arteriosclerosis or vascular insufficiency. We might inquire about the radiation of pain in the chest. Radiation to the back comes from certain mediastinal lesions.

Loss of weight, presumably, is determined by reduced dietary intake. Of course, a patient who cannot swallow anything is going to lose weight.

The sedimentation rate was 23 mm in one hour. Is that a normal rate?

Dr MARIAN W. ROPES: That is a definite increase in sedimentation rate.

Dr CHURCHILL: What I should like to know is whether that rate was normal for a woman seventy-six years of age who was losing a good deal of weight.

Dr ROPES: The sedimentation rate should not be elevated because of weight loss.

Dr CHURCHILL: But you are not sure?

Dr ROPES: No.

Dr CHURCHILL: I do not like the word "partial" fixation of the diaphragm. I consider fixation an absolute term. The diaphragm either was fixed or it was not fixed. Is there any further statement about that in the record?

Dr STANLEY M. WYMAN: The diaphragm was fixed peripherally but moved centrally.

Dr CHURCHILL: Then part of the diaphragm was fixed. The qualifying adjective "partial" refers to diaphragm, not to fixation. Would you mind showing us the films now?

Dr WYMAN: The single film of the chest available shows the right leaf of the diaphragm to be elevated. It was fixed laterally and moved much less freely centrally than the left leaf did. The area of density described is best seen in the right lower-lung field, it also shows in the right upper-lung field, where there seems to be localized consolidation or density in the region behind the second rib. The areas of fine linear density in the left lung field one might expect in a seventy-six-year-old woman. The heart is a little larger than normal, without characteristic configuration.

Dr CHURCHILL: Is there fluid in the right costophrenic angle?

Dr WYMAN: Yes, and possibly a small amount in the left.

Dr CHURCHILL: The left main bronchus was well seen, but the right was not visualized. Barium demonstrated narrowing in the esophagus.

Dr WYMAN: These spot films best demonstrate the area of narrowing of the esophagus, just below the carina. The narrowing appears to be distensible and to change in contour, suggesting that it is flexible. The left main bronchus is well seen on the spot films, but the right is not visualized beyond the bifurcation of the trachea. In this view a short segment of the right main bronchus is seen that seems to taper. I can see no evidence of ulceration of the esophageal mucosa and no shelf formation.

Dr CHURCHILL: What is shelf formation?

Dr WYMAN: It is the term used to describe, somewhat inaccurately, the margin of a tumor mass, which may represent intrinsic or extrinsic tumor pressing on the esophagus or growing in the wall. It is seen, unfortunately, in inflammatory conditions also and is not, per se, a sign of tumor.

Dr CHURCHILL: The passage of barium was delayed, but there was no true obstruction?

Dr WYMAN: That is correct.

Dr CHURCHILL: The films of the stomach show how easily barium filled the stomach.

Dr WYMAN: We have a satisfactory examination of the stomach and duodenum. The esophageal delay is apparent in the spot film taken in the upright position. The esophagus can be seen proximal to the narrowing. It is not dilated as in a true obstruction. The stomach itself shows no disease. The duodenal cap and proximal duodenal loop are normal except for a diverticulum. There

are a few areas of calcification in the region of the right kidney, which are probably renal calculi

DR CHURCHILL Laminograms of the right lower-lobe bronchus were done. May we see them?

DR WYMAN This is the film that shows the lesion best, although it is not ideal. One can trace the left main bronchus quite readily and the right main bronchus for a short distance from the bifurcation. The upper-lobe bronchus is seen coming off and it appears of good contour. The lower-lobe bronchus is poorly visualized and is definitely narrowed in a fusiform manner. I cannot make out a mass in this region. The pleural fluid has increased considerably since the first observation.

DR CHURCHILL Later on, dullness is described over the entire right side of the chest, with absent breath sounds in the upper third. The physical findings were therefore changing, and there was increased fluid in the chest.

DR WYMAN Yes.

DR CHURCHILL This woman was bronchoscoped, and it was observed that she had a concentric constriction of the right middle-lobe orifice. No biopsy was obtained at that time. Later, an esophagoscope was passed, and a biopsy obtained. The report of "doubtful" is of no help.

This history is obviously a trap. There are just enough findings in it that are atypical for carcinoma to make one reluctant to swing with the laboratory to a positive diagnosis of cancer. First of all, the x-ray peculiarities have been pointed out and, also, the negative findings on both bronchoscopy and esophagoscopy. If we are to resolve the problem by a diagnosis of tumor on the basis of the identification of tumor cells in the sputum, we must postulate a primary tumor in the bronchus, with secondary mediastinal involvement by metastatic disease. Cancer, primary in the esophagus, may involve the left primary bronchus. It does not involve the right primary bronchus below the level of the middle-lobe bronchus unless extraordinarily far advanced. The diagnosis of cancer of the esophagus has been made by bronchoscopy when the tumor was penetrating the left primary bronchus. But I doubt on anatomic grounds that the primary growth by direct invasion would pick off these two areas. One possibility, then, is primary bronchiogenic carcinoma in the right lung, with mediastinal extension or metastases producing secondary obstruction to the esophagus. Another is that this whole picture was caused by metastases from a primary focus elsewhere in the body. We have seen cancer of the cervix — a very small early carcinoma of the cervix — manifest itself by obstruction to the esophagus in just this area by spreading up through the retroperitoneal lymph nodes to the mediastinal lymph nodes. No mention is made of an extra-thoracic focus of neoplasm in the case under discussion. I do not know whether or not complete physical examination included visualization of the

cervix and precise examination of other likely areas of primary neoplasm in a woman of this age. We would like to see a statement that the breasts, for example, were not involved. We have to assume that the physical examination was complete and negative.

So far as differential diagnosis between neoplasm and inflammation is concerned, there is a great deal in favor of inflammation, particularly the nature of the lesion of the esophagus. It is described as a long, attenuated lesion, without obstruction. It is as though the esophagus were being gripped in a chronic, sclerosing, inflammatory lesion. What that could be is hard to say. We do know that tuberculosis produces such a lesion. We have had cases at these conferences in which tuberculosis of the mediastinum caused a similar picture. It is likely to occur in elderly persons. In favor of tuberculosis is the apical lesion pointed out by x-ray examination. The other lesions in the lung parenchyma could have been caused by esophageal regurgitation with food and mucus running down the windpipe and producing pneumonitis in this area of the lung. It would not account for the fluid in the pleural space unless there was an active pneumonia. There should also have been some signs of invasive infection from pneumonia.

Sputum examination was negative for tubercle bacilli but positive for tumor cells. On that evidence we must take the position that this lesion was not inflammatory but neoplastic. The statement that tumor cells have been demonstrated in the sputum is a definite one. There are cases in which the cytologic evidence can be taken as positive evidence. There are others in which we may have to put cytologic findings on a par with other clinical findings. Malignant cells were demonstrated in the sputum, so that the diagnosis must conform to that evidence and we must take the position that this woman had a cancer. All we can do is point out that there are many aspects of this case in which, in the absence of that finding, we would incline toward an inflammatory lesion — tuberculosis. Except for tuberculosis it is very difficult to picture an inflammatory lesion with a normal white-cell count and a normal temperature producing this type of process. The accumulation of fluid worries me a little, whatever diagnosis we accept. I wish we knew what it was — whether it had been aspirated, which would be another chance to demonstrate tumor cells, if it was a carcinoma.

With the evidence as presented, we can do no more than say that positive evidence of malignant cells, with the story and x-ray findings, allows no other tenable diagnosis than cancer. I expect it to be primary in the right bronchial tree, involving the esophagus by direct invasion and metastatic spread. In the absence of the positive findings of a malignant lesion, I would have leaned toward an inflammatory lesion, most likely tuberculosis.

A PHYSICIAN How about the syncope?

DR CHURCHILL It is described as syncope following a fall. I suspect that the fall was caused by the syncope. A cerebral arteriosclerosis was manifested in the hospital by memory defect.

A PHYSICIAN Could it have been tumor of the brain?

DR CHURCHILL Without localizing signs, I would not make a diagnosis of such a tumor.

DR KING These reports on tumor cells are checked by the head of the Vincent Laboratory, who has had much experience with this procedure, and when the report comes back positive I hate to throw it out. I think in this case the report came through very late in the course of study, but it did corroborate our opinion that the disease was neoplastic and not inflammatory. Where it had originated, we could not tell. The patient was too sick to go through many examinations to determine the source. She developed fluid quite rapidly just before death.

#### CLINICAL DIAGNOSIS

Carcinoma of esophagus

#### DR CHURCHILL'S DIAGNOSIS

Bronchiogenic carcinoma, primary in right lower lobe, with secondary involvement of esophagus  
Cerebral arteriosclerosis?

#### ANATOMICAL DIAGNOSES

*Bronchiogenic carcinoma, right lower-lobe bronchus, with extension to esophagus and metastases to mediastinal lymph nodes, liver and omentum*  
Thrombosis of pulmonary artery, right lower lobe  
Arteriosclerosis, generalized, severe  
Hydrothorax, bilateral  
Duodenal diverticulum

#### PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY Autopsy showed extensive carcinoma, and the problem to be settled is where it was primary. The two largest masses of tumor were found in the right lower lobe and an annular mass that encircled the esophagus. There was a secondary, entirely separate lesion of the esophagus as well. The tumor in the esophagus had invaded and involved the scrota and muscularis but at no point the mucosa, and there was no point of ulceration, which would be extremely unusual in a primary cancer of that area. The right lower-lobe bronchus was completely surrounded by tumor, and there was widespread extension of the tumor through the lung via the lymphatic channels. The findings there were consistent with primary bronchiogenic carcinoma of the right lower-lobe bronchus. Although no point of ulceration in the bronchial mucosa could be demonstrated, the bronchus became rapidly and completely stenosed.

Histologic examination, which does not help us any further, disclosed a wildly undifferentiated tumor, and it is quite impossible to say whether it arose from squamous or glandular cells. A few of the cells were vacuolated and might suggest mucin production, but we were unable to prove that to our satisfaction. There were metastases in the mediastinal lymph nodes, in the mesentery and in the liver. We were not able to examine the brain, so that we cannot say whether it contained metastases. Our final diagnosis was bronchiogenic carcinoma, right lower-lobe bronchus, with secondary involvement of the esophagus.

DR CARROLL C MILLER Did the X-ray Department believe that the haziness and the irregular areas represented lymphatic spread?

DR WYMAN The original interpretation was that the haziness in the right lung was suggestive of lymphatic metastases.

## SAVING THE NEWBORN INFANT

A COMMUNICATION published elsewhere in this issue of the *Journal* calls attention to a most progressive step that has been taken in behalf of the newborn infant. This step, another important undertaking of the American Academy of Pediatrics, is the establishment in every state of the union of committees to develop and improve facilities for the hospital care of newborn infants.

The need for this action was indicated by Dr. Stewart H. Clifford\* in a paper read before the Massachusetts Medical Society in May, 1947, calling attention to the greatly increased demand for hospitalization of obstetric patients and the alarming increase in communicable diseases of the newborn.

\*Clifford, S. H. Diarrhea of newborn. *New Eng J Med.* 237: 969-976, 1947.

Dr. Clifford is chairman of the central committee on the fetus and newborn of the American Academy of Pediatrics.

These new committees wield no rubber stamps. They are out to produce results, both on their own initiative and in holding up the hands of public-health authorities. In Massachusetts the Department of Public Health has been preparing a new set of regulations for nursery construction and operation. The state committee will participate in such planning, and will co-operate in every other way with the Department.

As a useful guide to be followed voluntarily by hospitals until such time as these regulations may be put in force, Regulation 35 of Chapter II of the New York State Sanitary Code, enacted in January, 1948, is recommended for use, and is printed in the communication to which reference has been made. This regulation embodies the best known precautions that may be used for the control of diarrhea of the newborn infant.

## CANCER-DETECTION CLINICS

IN THE desire to do all possible in controlling cancer there have been evolved several types of cancer-detection clinics, and a great popular interest has been engendered in them. In fact any state that does not contain one or more of these clinics tends to be looked upon as decidedly backward in its cancer program. Forty of the states now have clinics of this type, and some four hundred of them exist altogether.

Both the American Medical Association and the American College of Surgeons have recognized the desirability of these clinics and have laid down certain principles for their establishment and operation.

The purpose of the clinics is essentially to examine healthy persons to determine whether or not they are harboring precancerous conditions, early cancer or other incipient pathologic processes. An analysis of the clinics was presented at the annual meeting of the New England Surgical Society on October 4, 1947, by Dr. Charles L. Larkin, of Waterbury, Connecticut, who pointed out a number of fallacies in the fundamental thesis of their operation.

To carry out annual examinations of the type proposed by some enthusiasts would require the entire time of every doctor in the United States, according to Dr Larkin. The cost would be at least one and a quarter billion dollars a year. The clinics as operating at the present time defeat their very purpose in that prospective examinees are booked for months ahead, and hence delay is encouraged should any symptoms appear in the interim.

The popularity of these clinics however, is so great that in all probability, since Massachusetts is one of the few states that does not have one, one or more will be organized by lay groups if the medical profession does not act.

There is no question that the most effective place for a cancer-detection examination is the office of the private physician. However, it is far from certain what types of diagnostic procedures are best suited to detect early cancer and what costly accessory services, such as x-ray and laboratory procedures, are warranted.

There has been proposed by the staff of the Palmer Memorial Hospital and recommended by the Committee on Cancer of the Massachusetts Medical Society and approved by the Council of the Society the establishment of a new type of cancer-detection clinic at the Palmer Memorial Hospital. This clinic would have as its primary purpose not the examination of a few hundred persons a year to determine whether or not they had cancer, which would be of little significance in the over-all problem, but rather would attempt to determine procedures in cancer diagnosis that would be of value to the practitioner and would so evaluate the laboratory and x-ray services as to enable those most useful to be selected and to avoid the expense of a wide range of laboratory and radiologic procedures.

It is important to keep in mind that all a cancer-detection clinic provides is an opportunity for a thorough physical examination with ancillary services. Properly organized, these clinics do not conflict with already existing tumor clinics or cancer clinics because the detection clinics are concerned primarily with healthy persons whereas the patients referred to the cancer clinic or tumor clinic already have developed a lesion.

A cancer-detection clinic of the type suggested for the Palmer Memorial Hospital might well not only be a very real asset to the practicing physician but also set a more realistic and practical pattern for such clinics throughout the country.

## A STEP FORWARD

A MEDICAL rehabilitation clinic in Boston has been planned, and a petition requesting incorporation has been filed. The purposes of the proposed clinic are as follows:

To maintain a charitable medical rehabilitation clinic or clinics for the benefit and treatment of convalescent patients to assist in the restoration of such patients to gainful economic independence to maintain facilities for the evaluation restoration and improvement of the remaining physical abilities of persons crippled or handicapped as a result of war, disease, accident or other causes referred to it by government and civilian hospitals, industrial and other clinics and by members of the medical profession.

This new type of medical clinic was originally conceived by one of our ablest and most respected statesmen, Mr. Bernard M. Baruch. He recognized the gap that existed in medical care between the time the patient left the hospital and the time he resumed normal routine productive activity. In 1944 he established The Baruch Committee on Physical Medicine,<sup>2</sup> which, working with a civilian scientific advisory committee and with representatives of the surgeons general of the armed forces, developed a plan based on the program of convalescent training and reconditioning treatment in military and naval hospitals, but also applicable to civilian communities. In 1946 the report on A Community Rehabilitation Service and Center<sup>3</sup> was published by the Baruch Committee on Physical Medicine. This stimulated in communities great interest toward the establishment of medical facilities or clinics that might specialize in the treatment of the seriously disabled convalescent patient.

New York University College of Medicine has already established a Department of Rehabilitation with Professor Howard A. Rusk as chairman. He will direct the project planned as part of the New York University-Bellevue Hospital Medical Center. The College of Physicians and Surgeons of Columbia University has placed Dr. Frank E. Sunchfield in charge of its recently affiliated Institute for Crippled

and Disabled Toronto, Canada, has a state-operated rehabilitation center that appears to be functioning not only for medical treatment of convalescence but also for active vocational guidance and training. Cleveland and Milwaukee have had rehabilitation workshops operating successfully for a number of years. Bridgeport, San Francisco and Kansas City have, or are now establishing, rehabilitation centers. Although Boston has one medically supervised rehabilitation center operated for the benefit of the clients of one insurance company only,<sup>4</sup> it needs one open to the public.

The Council of the Massachusetts Medical Society passed a resolution on May 24, 1947, recognizing the need for a rehabilitation center in Boston. Pursuant to this resolution, on February 26, 1948, a petition requesting the incorporation of The Bay State Medical Rehabilitation Clinic was filed with the Department of Public Welfare. The authorities are urged to grant this petition, so that the Commonwealth may have an opportunity to provide for its physically handicapped citizens some of the newer concepts of medical rehabilitation. The Division of Vocational Rehabilitation of the Department of Education could utilize the services of this new nonprofit private charity. The charter provides for the training of personnel, many of whom will be qualified to staff similar centers in other communities. The disabled citizens of Massachusetts should have medically supervised rehabilitation services as good as or better than those of other states. There is no reason why this new type of medical charity should not be granted incorporation promptly.

Many permanently disabled citizens can be rehabilitated to gainful economic self-sufficiency. It takes courage to start a new charity at the present time. The Commonwealth will benefit by the establishment of such a clinic. The people of Boston need this medical service.

### DEATHS

McOWEN — William H. McOwen, M.D., of Newton Upper Falls, died on March 9. He was in his eighty-seventh year. Dr. McOwen received his degree from Harvard Medical School in 1883. For sixty years he was a member of the staff of Newton Hospital.

Four daughters, two sons, seventeen grandchildren and two great-grandchildren survive.

ROBINSON — Leon J. Robinson, M.D., of Palmer, died on February 1. He was in his forty-second year.

Dr. Robinson received his degree from Boston University School of Medicine in 1934. He was a member of the staff of Monson State Hospital and was a fellow of the American Medical Association.

Two sisters survive.

## MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

### PROPER USE OF GAMMA GLOBULIN

The decision of the physician to use gamma globulin to prevent measles calls for the critical consideration of many factors. The indiscriminate use of the material on all children who have been exposed to measles is entirely unwarranted. Indications for various age groups may be summarized as follows: under six months prevention is unnecessary if the mother has had measles but is indicated if there is no history of measles in the mother, six months to three years (measles is most dangerous in this period) prevention is recommended, and over three years (measles is relatively mild with present available therapy) prevention is never justified, except in special circumstances such as sick or debilitated persons of any age or in children's institutions or hospital wards where it causes many cross infections. The use of gamma globulin for modification of measles in this or older age groups is justified.

Measles in a healthy child almost always confers lifelong immunity and causes at the most a loss of two weeks' play or school in the lower grades. Passive prevention at this age may mean that the person will later have measles — perhaps more severely as an adult — at a time when it can mean the loss of a semester's work in high school or college, or serious loss of employment.

The use of gamma globulin in other diseases, for which no evidence of efficacy has accumulated, is considered a waste of a very expensive product. Present stocks are derived almost entirely from fractionation of the large amounts of surplus plasma left over from the wartime Red Cross plasma program. This globulin should be conserved, since there is as yet no source of whole blood in view sufficiently large to supply future needs. If present supplies are exhausted, physicians will be obliged

to purchase the globulin, since the Department of Public Health has no funds for this purpose.

A circular giving more detailed information regarding the use of gamma globulin will be furnished on request to the Division of Biologic Laboratories, 375 South Street, Jamaica Plain 30, Massachusetts.

## MISCELLANY

### FEDERAL SECURITY AGENCY CHILDREN'S BUREAU

Dr. Samuel M. Wishik, formerly of the New York City Health Department, has been appointed to the Children's Bureau of the United States Federal Security Agency to direct the planning work connected with the Bureau's program of grants-in-aid to the States for maternal and child health and for crippled-children's services.

In announcing the appointment Dr. Martha M. Eliot, associate chief of the Children's Bureau, said that more effective health services are needed for the thousands of babies born prematurely and the children suffering with cerebral palsy, rheumatic fever, hearing defects, cleft palate and many other handicaps.

### ATOMIC ENERGY COMMISSION CANCER RESEARCH

The Atomic Energy Commission, according to a Washington Report on the Medical Sciences, has released its plans for the expenditure of \$5,000,000 that it received from Congress last fall for cancer research. Most important of its activities will be provision of free radioisotopes to qualified handlers in approved institutions, financial support of research projects in hospitals, clinics and universities, establishment of cancer investigation facilities at four Commission-operated laboratories and continued aid to the Committee on Atomic Casualties of the National Research Council. This committee is investigating long-term effects on survivors of the Nagasaki and Hiroshima bomb explosion.

### AMERICAN PSYCHIATRIC ASSOCIATION

Dr. Daniel Blain, formerly chief of neuropsychiatric services for the Veterans Administration, has accepted the newly established position of medical director of the American Psychiatric Association. The position has been created to provide the full-time services of a physician who will act for the Association as an authorized source of information and advice.

As medical director, Dr. Blain will make his services available to the members, to affiliate societies and to public and private organizations interested in the field of psychiatry. He will serve also to effect liaison with the public on subjects related to the work of the Association and to the general interests of society.

For the present, Dr. Blain may be addressed at Georgetown University Hospital, Washington, D. C. or at the executive office of the American Psychiatric Association, Room 924, 9 Rockefeller Plaza, New York City 20.

### APPOINTMENT OF SOCIAL-SERVICE WORKER AT HARVARD SCHOOL OF PUBLIC HEALTH

As part of a new program to study the role of family life in the health of children, the Harvard School of Public Health recently announced the appointment of Miss Eliza Beth P. Rice, at present clinical professor of the social aspects of medicine at Yale University School of Medicine and assistant professor of the social aspects of nursing at the Yale School of Nursing as the first social-service worker to the faculty.

As assistant professor of medical social work in the Department of Maternal and Child Health, Miss Rice will begin a study of the preventive aspects of social work. Particular

emphasis in the new program will be placed on the role of the family in preventing the development of undesirable social habits in children. Also, attention will be directed to discovering unfavorable social factors as they relate to the health of the family.

Miss Rice, a native of Boston, received the A.B. degree from Wellesley College and the A.M. from Simmons College. Among the positions that she has held in the field of medical social work are assistant director of the Social Service Department, Boston City Hospital and director of social service, Boston Dispensary, the New Haven Hospital and the Grace-New Haven Community Hospital. She is the author of several publications on the part that medical social work plays in medicine and nursing.

## PROGRESS IN DENTAL MEDICINE

The Division of Dental Health of the Massachusetts Department of Public Health has completed the first year of its existence. During this period six studies concerned with the prevention of dental caries were in operation and water-fluorination programs were established in the Belchertown and Wrentham State schools with the Fernald State School as a control.

At the Daniel Butler School in Belmont a project has been started with the use of indium nitrate as a substitute for the fluorine salts in topical applications. In Brockton a study was set up on the effect of fluorine incorporated in dentifrices, in Medford one on the use of fluorine in mouth washes and in Quincy one on the incorporation of fluorine in prophylaxis pastes to be used twice yearly on a group of children.

At the Harvard School of Dental Medicine the announcement has been made of the promotion of Dr. Reidar F. Sognnaes, an authority on dental decay, to an associate professorship of dental medicine.

## CORRESPONDENCE

### COMMITTEE ON FETUS AND NEWBORN INFANT

To the Editor: The following physicians have been appointed by Dr. James M. Baty, state chairman of the American Academy of Pediatrics, to serve as a Massachusetts Committee on the Fetus and Newborn Infant: W. Bradford Adams, Springfield; Fred H. Allen, Holyoke; Joseph Garland, Boston; Paul J. Jakma, South Boston; Robert T. Moulton, Salem; Alfred S. O'Connor, Worcester; Herman Petterson, Boston; Clement A. Smith, Boston; Stuart F. Stevenson, Boston; and Alfred Weller, Arlington Heights. It is felt that readers of the *Journal* should be informed about the existence and function of this committee.

The American Academy of Pediatrics is setting up in all the states committees similar to this one with the purpose of developing and improving facilities for the hospital care of newborn infants—full term and premature. These committees will act in co-operation with the state and local public health authorities as representatives of the practice of pediatrics as it touches related interests in this field. Although many of the problems to be attacked will not be those of infectious diseases in the newborn period, the prevalence of sporadic epidemics of diarrheal disease in newborn nurseries will obviously turn a considerable part of the committee's attention to that special subject.

Dr. Stewart H. Clifford, chairman of the Academy's national committee in this field, has called attention to the recently approved New York State Sanitary Code bearing upon diarrhea of the newborn. Dr. Clifford and members of the committee believe that the New York statement is so admirably succinct and complete that it is transmitted as deserving publication. It has obviously no legal status in Massachusetts but covers the problem so well that it might be highly useful to any hospital or physician faced with the prevention or management of an epidemic and is offered only with this purpose. The code is as follows:

#### CHAPTER II

Regulation 35. Precautions to be observed for the control of diarrhea of the newborn. It shall be the duty of administrators of general hospitals or child caring institutions, proprietors of maternity hospitals or maternity

homes, and physicians and nurses responsible for the care of normal newborn and premature infants in general hospitals or child caring institutions, or maternity hospitals or maternity homes, to take all reasonable precautions to prevent the introduction and spread of diarrhea of the newborn, including the following

- a Formulae and other fluids offered to newborn infants in hospitals or child caring institutions, or in maternity hospitals or maternity homes shall be poured into individual feeding bottles at the time of preparation, and a nipple shall be attached to each bottle and covered with a cap. The entire product shall then be subjected to terminal heating by steam under pressure of not less than 15 pounds (121° Centigrade or 250° Fahrenheit) for not less than 5 minutes, or at a pressure of not less than 6 pounds (110°C or 230°F) for not less than 10 minutes, or by flowing steam at a temperature of not less than 100°C (212°F) for not less than 30 minutes. The temperature of the formula or fluid, as determined by periodic examination, shall be not less than 93°C (200°F) at the end of the heating process. The nipple cap shall remain on the bottle until the time of feeding. If fruit juices, or formulae containing lactic acid, meats, or cereals are given to newborn infants, they may be offered without such terminal heating, but shall be prepared with and stored in pre-sterilized equipment.
- b Normal newborn and premature infants born in a hospital or maternity hospital or maternity home shall not be kept in the same nursery, room or ward with sick infants or older children. Nurses giving care to infected patients shall not come in contact with infants in the normal newborn or premature infant nurseries. No infant born outside the hospital or maternity hospital or maternity home shall be admitted to the nursery for well infants, except after isolation for a period of one week. An infant born to a mother who has diarrheal or respiratory illness shall not be admitted to the nurseries for normal newborn or premature infants.
- c An infant suspected of having diarrhea of the newborn shall be promptly removed from the normal newborn or premature infant nurseries, and kept under isolation precautions. If, after observation, diarrhea of the newborn is found to exist, such infant shall then be transferred to an isolation nursery.
- d Individual equipment shall be provided for each infant except for the weighing scales, which shall be freshly covered for each infant. Common bathing and dressing tables are prohibited. The use of racks, carriers, or bassinet stands for holding or transporting more than one infant at a time is prohibited. Physicians and nurses shall wash their hands under running water before and after coming in contact with any infant.
- e Nursing care shall be given to each infant at the bedside. Space shall be adequate to give such care, provided that the total nursery floor space shall average not less than 24 square feet per infant, or the infants shall be placed in individual cubicles.
- f No room used as a nursery shall house more than 12 infants, nor shall such a room intercommunicate with other rooms used as nurseries. There shall be running hot and cold water for handwashing in each room used as a nursery, with the flow of water controlled by elbow, knee or foot valves. No nurse shall give care to more than 12 infants and their equipment.

Enacted January 16, 1948, to be effective January 1, 1949, except that the enforcement of either or both subdivisions "e" and "f" may be deferred for an individual institution for a period not later than January 1, 1951 by the State Commissioner of Health upon request of such institution.

The Massachusetts Committee on the Fetus and Newborn Infant, or its individual members, will welcome any opportunity to assist in planning for nursery construction or in giving informal advice regarding any problems concerning the health of newborn infants in the Commonwealth.

CLEMENT A. SMITH, M.D., *Chairman*

Boston

## BOOK REVIEW

*Diseases of Children* Edited by Donald Paterson, M.D. (Edin.), F.R.C.P., and Alan Moncrieff, M.D. (Lond.), F.R.C.P. Volume I, with contributions by twenty-nine authors. Fourth edition. 8°, cloth, 771 pp., with 154 illustrations. Baltimore: Williams and Wilkins Company, 1947. \$9.00.

This first volume of a standard treatise, first published in 1913 in a single volume, is the joint work of twenty-nine English specialists in their particular fields. The third edition was issued in 1934, and a new edition planned before the outbreak of World War II had to be abandoned because of hostilities and consequent difficulties. This fourth edition has been expanded into two volumes, and the text and illustrations thoroughly revised to bring them up to date. Sections have been added on the surgical aspects of congenital deformities, growth and development, the use of drugs in infancy and childhood, including the sulfonamides and penicillin, clinical pathology, acid-base regulation, anesthetics in the surgery of childhood, subdural hematoma in infancy, the treatment of megacolon, abdominal pain, surgery of the lung, treatment of pneumonia, diagnosis and treatment of collapse of the lung, and much new material on tuberculosis. The volume is divided into two parts, general considerations and diseases of children, including diseases and injuries of the newborn, diseases of nutrition, metabolism, the ductless glands, the digestive tract, the respiratory system, tuberculosis and allergy. Selected references are appended to each chapter. A good index concludes the volume. The book is well published. It is recommended for all medical libraries and should prove valuable to all physicians interested in pediatrics.

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*Approaches to Tumor Chemotherapy* A symposium of papers and discussions on various aspects of tumor chemotherapy, developed from the summer meetings of the Section on Chemistry (C) of the American Association for the Advancement of Science at Gibson Island, Maryland, 1945-1946. Edited by Forest Ray Moulton. 4°, cloth, 442 pp., illustrated. Washington: The Association, 1947. \$7.75.

Twenty-six main articles make up this special volume. Ninety-three specialists took part in the meetings in 1945 and 1946, and the main papers are included in this volume. The first part is a general review of cancer therapy. The second presents a series of papers on special methodology; the third, nutritional factors; the fourth, bacterial products; the fifth, nitrogen mustards; and the sixth, various clinical aspects. This series of papers reflects the current knowledge on the subject. The volume is well published in every way. It is recommended for all medical libraries, and should prove valuable to all physicians interested in tumors.

*Entwicklungsgeschichte des Krankheitsbegriffes* By Dr. Emanuel Berghoff. Second edition. 8°, cloth, 201 pp. Wien, Verlag Wilhelm Maudrich, 1947. \$5.00. *Wiener Beiträge zur Geschichte der Medizin* Vol. I. Distributed in the United States by Grune and Stratton, New York.

This monograph on the historical development of the ideas of disease discusses in order the significance of pre-Hippocratic ideas and the early theories of disease, Hippocrates and his school, Galen and the Middle Ages, the Renaissance and the seventeenth century, followed by chapters on animism and neuropathology, mesmerism and the Romantic school, the period of the end of the eighteenth and the beginning of the nineteenth centuries, the Vienna School, and cellular pathology and the bacteriologic era, serology and constitutional pathology. The work concludes with a chapter on the significance of social medicine in relation to disease ideas. The volume is concluded with a short list of references and an author index. An index of subjects would be appreciated in

a succeeding edition. The text is well arranged and well written. The type and paper are good and the printing is well done. The publication is up to the standard of prewar days. The monograph is recommended for all medical history collections.

*How Life is Handed On.* By Cyril Bibby M.A. M.Sc., F.L.S., senior lecturer, College of St. Mark and St. John, London. 8, cloth, 159 pp., with 62 illustrations. New York: Emerson Books Incorporated, 1947. \$2.00.

This small book is intended for the use of children and young adolescents. The text is written in so easy a style brought down to the educational level of the intended readers. The descriptions of the beginnings of life in animals and man are presented in a frank manner. There are additional chapters on the relation of the sexes, family life and adolescence as well as on the declining birth rate. The appendices contain a list of simple biologic experiments, books for further study and a glossary of terms used in the text. There is an index of plant and animal names and one of subjects. The author does not set any minimum limit on the age of children for which the book is intended, therefore it would be advisable for parents to pass on the book before giving it to their children. The printing, type and paper are good and the price is reasonable.

*Successful Dental Practice. Patient relations patient education—training planning—business principles.* By J. Lewis Blass, Ph.D. D.D.S., associate professor of periodontology, lecturer on practice management and lecturer on dental therapeutics, New York University College of Dentistry, and Irvin Tullin D.D.S. 8, cloth, 221 pp., with 42 illustrations, including 16 color plates. Philadelphia: J. B. Lippincott Company, 1947. \$6.00.

The authors write in detail on the management of patients, office management fees, insurance, legal matters and other problems that effect the business of a dental practice. The text is concluded with an atlas for patient education. A good index completes the volume. Valuable suggestions are presented for the improvement of the business side of practice, some of which could be of value to physicians, especially those relating to patient management. The volume is well published.

*Practical X-ray Treatment.* By Arthur W. Erskine M.D. Third edition revised and enlarged. 8, cloth, 155 pp. with 22 illustrations. Saint Paul: Bruce Publishing Company, 1947. \$4.50.

The first edition of this manual was published in 1931 and the second in 1936 and this revision of 1947 seeks to correct the mistakes made in the preceding editions. The text is devoted to the methods used by the author in the treatment of skin diseases, infections and inflammations, nonmalignant conditions, such as hyperthyroidism, hypertrophy of the tonsils, scrofula and fibroid tumors and cancer and malignant conditions. The first eight chapters deal with technique, dosage and effects on tissue. The chapter on scattering and distribution is illustrated with fourteen tables showing the back-scatter and distribution of x-rays of various degrees of quality under various physical conditions. The volume is well published in every way and should prove useful to physicians interested in the subject.

*Osteophthysis Pelvis et Femoris. Zugleich ein Beitrag zur Frage der spontanen Rückbildung malignanter Tumoren.* By Dr. Gottfried Hartmann, Assistent des pathol. anat. Institutes der Universität Wien. 8, cloth, 183 pp., with 19 illustrations. Wien: Verlag Maudrich, 1947. \$5.00. Distributed in the United States by Grune and Stratton, New York. *Wiener Beiträge zur Pathologie und pathologische Anatomie. Vol. I.*

This monograph on tuberculosis of the pelvis and femora is based on a complete study, clinical, roentgenologic, pathologic and histologic, of a fatal case in which both hips were involved. The patient was studied for a period of ten years. The histologic study of all tissues of the body after autopsy is comprehensive and is considered in the light of the question of spontaneous involution of malignant tumors. The text is divided into six parts: a short prologue followed by

the case history, a critical study of the histologic materials including an interpretation of the findings, the etiology and pathogenesis of the condition and its problems, and a summary. The text concludes with a list of references. An index would be appreciated. The publishing is well done in every way. The histologic plates are excellent. The monograph should be in all large medical libraries.

*La Médecine au Etats Unis de 1940 à 1946.* By Dr. Stanislas Lassalle in collaboration avec Dr. A. Gottschalk. 8, paper, 333 pp. Paris: Editions Hippocrate, 1946. 270 francs.

This volume consists of abstracts of the principal articles published in American medical periodicals during the period 1940-1946. Eighty-three different journals were consulted and the coverage is good. The emphasis is on therapeutics and clinical medicine. The subjects of gynecology, obstetrics, pediatrics, surgery and experimental medicine are also included. The abstract is well done and the book should prove valuable to French speaking physicians.

*Introducción al Estudio de la Plasmoterapia.* By Jose M. Masons de la Sección de farmacología del Instituto de Investigaciones Médicas de la Universidad de Barcelona. Prologo de Francisco Garcia Valdecasas. Catedrático de farmacología de la Facultad de Barcelona. 12, paper, 276 pp., with 15 illustrations. Barcelona: Editorial Miguel Serret, 1947.

This valuable monograph on the use of blood plasma is essentially a review of the world's literature through the year 1945. The author, after a chapter on history, discusses in order: physiopathology, hypoproteinemia and protidopenia, human and animal plasma and colloidal solutions, the indications of the use of plasma, the technique of its administration and the complications. The text is well organized and well written. The type and paper are excellent. Good indexes of authors and subjects conclude the volume. The monograph should be in all large medical libraries and should prove valuable to all persons interested in the subject.

*Headache.* By Louis G. Moench M.D., assistant clinical professor, University of Utah School of Medicine and internist, Salt Lake Clinic, Salt Lake City. 8, cloth, 207 pp., with 58 illustrations. Chicago: Year Book Publishers, Incorporated, 1947. \$3.50.

The researches of recent years have advanced greatly the knowledge of the troublesome symptom of headache. Dr. Moench has brought together in one volume for ready reference the latest ideas on the subject. He classifies the material according to the origin of the symptom: pathological anatomy and physiology followed by headache from intracranial disease, spinal puncture and ventriculography, cranial nerve neuralgias, headaches of ocular and nasal origin, from disease in the neck and from systemic disorders, histamine headaches, migraine, and headaches of emotional origin. A list of references is appended to each chapter, and a good index concludes the volume. The material is well organized. The printing is well done with a good type on good paper. The book is recommended for all medical libraries and should prove useful to the general practitioner for whom it is written.

*Neutron Effects on Animals.* By the staff of the Biochemical Research Foundation. Dr. Ellice McDonald, director, Newark, Delaware. 8, cloth, 198 pp. Baltimore: Williams and Wilkins Company, 1947. \$3.00.

The cyclotron employed in these researches was specially constructed for biochemical and biologic study. During an investigation on the blood for the Manhattan District it ran continuously for more than a year without missing a day. For the past eight years the staff of the Foundation has been studying the forces and material produced by the machine. The twenty papers presented in this volume represent the preliminary studies on the effects of neutrons on body tissues and fluids of the lower animals. The volume is well published in every way, and its price is reasonable. This is a book in a new field and is recommended for all medical libraries.

homes, and physicians and nurses responsible for the care of normal newborn and premature infants in general hospitals or child caring institutions, or maternity hospitals or maternity homes, to take all reasonable precautions to prevent the introduction and spread of diarrhea of the newborn, including the following

- a Formulae and other fluids offered to newborn infants in hospitals or child caring institutions, or in maternity hospitals or maternity homes shall be poured into individual feeding bottles at the time of preparation, and a nipple shall be attached to each bottle and covered with a cap. The entire product shall then be subjected to terminal heating by steam under pressure of not less than 15 pounds (121° Centigrade or 250° Fahrenheit) for not less than 5 minutes, or at a pressure of not less than 6 pounds (110°C or 230°F) for not less than 10 minutes, or by flowing steam at a temperature of not less than 100°C (212°F) for not less than 30 minutes. The temperature of the formula or fluid, as determined by periodic examination, shall be not less than 93°C (200°F) at the end of the heating process. The nipple cap shall remain on the bottle until the time of feeding. If fruit juices, or formulae containing lactic acid, meats, or cereals are given to newborn infants, they may be offered without such terminal heating, but shall be prepared with and stored in pre-sterilized equipment.
- b Normal newborn and premature infants born in a hospital or maternity hospital or maternity home shall not be kept in the same nursery, room or ward with sick infants or older children. Nurses giving care to infected patients shall not come in contact with infants in the normal newborn or premature infant nurseries. No infant born outside the hospital or maternity hospital or maternity home shall be admitted to the nursery for well infants, except after isolation for a period of one week. An infant born to a mother who has diarrheal or respiratory illness shall not be admitted to the nurseries for normal newborn or premature infants.
- c An infant suspected of having diarrhea of the newborn shall be promptly removed from the normal newborn or premature infant nurseries, and kept under isolation precautions. If, after observation, diarrhea of the newborn is found to exist, such infant shall then be transferred to an isolation nursery.
- d Individual equipment shall be provided for each infant except for the weighing scales, which shall be freshly covered for each infant. Common bathing and dressing tables are prohibited. The use of racks, carriers, or bassinet stands for holding or transporting more than one infant at a time is prohibited. Physicians and nurses shall wash their hands under running water before and after coming in contact with any infant.
- e Nursing care shall be given to each infant at the bedside. Space shall be adequate to give such care, provided that the total nursery floor space shall average not less than 24 square feet per infant, or the infants shall be placed in individual cubicles.
- f No room used as a nursery shall house more than 12 infants, nor shall such a room intercommunicate with other rooms used as nurseries. There shall be running hot and cold water for handwashing in each room used as a nursery, with the flow of water controlled by elbow, knee or foot valves. No nurse shall give care to more than 12 infants and their equipment.

Enacted January 16, 1948, to be effective January 1, 1949, except that the enforcement of either or both subdivisions "e" and "f" may be deferred for an individual institution for a period not later than January 1, 1951 by the State Commissioner of Health upon request of such institution.

The Massachusetts Committee on the Fetus and Newborn Infant, or its individual members, will welcome any opportunity to assist in planning for nursery construction or in giving informal advice regarding any problems concerning the health of newborn infants in the Commonwealth.

CLEMENT A SMITH, M D, *Chairman*  
Boston

## BOOK REVIEW

*Diseases of Children* Edited by Donald Paterson, M D (Edin), F R C P, and Alan Moncrieff, M D (Lond), F R C P. Volume I, with contributions by twenty-nine authors. Fourth edition. 8°, cloth, 771 pp., with 154 illustrations. Baltimore: Williams and Wilkins Company, 1947. \$9 00.

This first volume of a standard treatise, first published in 1913 in a single volume, is the joint work of twenty-nine English specialists in their particular fields. The third edition was issued in 1934, and a new edition planned before the outbreak of World War II had to be abandoned because of hostilities and consequent difficulties. This fourth edition has been expanded into two volumes, and the text and illustrations thoroughly revised to bring them up to date. Sections have been added on the surgical aspects of congenital deformities, growth and development, the use of drugs in infancy and childhood, including the sulfonamides and penicillin, clinical pathology, acid-base regulation, anesthetics in the surgery of childhood, subdural hematoma in infancy, the treatment of megacolon, abdominal pain, surgery of the lung, treatment of pneumonia, diagnosis and treatment of collapse of the lung, and much new material on tuberculosis. The volume is divided into two parts, general considerations and diseases of children, including diseases and injuries of the newborn, diseases of nutrition, metabolism, the ductless glands, the digestive tract, the respiratory system, tuberculosis and allergy. Selected references are appended to each chapter. A good index concludes the volume. The book is well published. It is recommended for all medical libraries and should prove valuable to all physicians interested in pediatrics.

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*Approaches to Tumor Chemotherapy* A symposium of papers and discussions on various aspects of tumor chemotherapy, developed from the summer meetings of the Section on Chemistry (C) of the American Association for the Advancement of Science at Gibson Island, Maryland, 1945-1946. Edited by Forest Ray Moulton. 4°, cloth, 442 pp., illustrated. Washington: The Association, 1947. \$7 75.

Twenty-six main articles make up this special volume. Ninety-three specialists took part in the meetings in 1945 and 1946, and the main papers are included in this volume. The first part is a general review of cancer therapy. The second presents a series of papers on special methodology, the third, nutritional factors, the fourth, bacterial products, the fifth, nitrogen mustards, and the sixth, various clinical aspects. The first eight chapters deal with technique, dosage and effects on tissue. The chapter on scattering and distribution is illustrated with fourteen tables showing the back-scatter and distribution of x-rays of various degrees of quality under various physical conditions. The volume is well published in every way and should prove useful to physicians interested in the subject.

*Osteophthysis Pelvis et Femorum. Zugleich ein Beitrag zur Frage der spontanen Rückbildung malignanter Tumoren*. By Dr. Gottfried Hartmann, Assistent des pathol. anat. Institutes der Universität Wien. 8°, cloth, 183 pp., with 19 illustrations. Wien: Verlag Mandrich 1947. \$5.00. Distributed in the United States by Gruene and Stratton, New York. *Wiener Beiträge zur Pathologie und pathologische Anatomie*. Vol. I.

This monograph on tuberculosis of the pelvis and femora is based on a complete study, clinical, roentgenologic, pathologic and histologic, of a fatal case in which both hips were involved. The patient was studied for a period of ten years. The histologic study of all tissues of the body after autopsy is comprehensive and is considered in the light of the question of spontaneous involution of malignant tumors. The text is divided into six parts: a short prologue, followed by

the case history, a critical study of the histologic materials, including an interpretation of the findings, the etiology and pathogenesis of the condition and its problems and a summary. The text concludes with a list of references. An index would be appreciated. The publishing is well done in every way. The histologic plates are excellent. The monograph should be in all large medical libraries.

*La Médecine en Etats Unis de 1940 à 1946*. By Dr. Stanislas Lasalle, en collaboration avec le Dr. A. Gottschalk. 8° paper, 333 pp. Paris: Editions Hippocrate 1946. 270 francs.

This volume consists of abstracts of the principal articles published in American medical periodicals during the period 1940-1946. Eighty three different journals were consulted and the coverage is good. The emphasis is on therapeutics and clinical medicine. The subjects of gynecology, obstetrics, pediatrics, surgery and experimental medicine are also included. The abstract is well done, and the book should prove valuable to French speaking physicians.

*Introducción al Estudio de la Plasmoterapia*. By Jose M. Massons de la Sección de farmacología del Instituto de Investigaciones Médicas de la Universidad de Barcelona. Prologo de Francisco Garcia Valdecasas. Catedrático de farmacología de la Facultad de Barcelona. 12° paper, 276 pp., with 15 illustrations. Barcelona: Editorial Miguel Serret, 1947.

This valuable monograph on the use of blood plasma is essentially a review of the world's literature through the year 1945. The author, after a chapter on history, discusses in order physiopathology, hypoproteinemia and protidopenia, human and animal plasma and colloidal solutions, the indications of the use of plasma, the technique of its administration and the complications. The text is well organized and well written. The type and paper are excellent. Good indexes of authors and subjects conclude the volume. The monograph should be in all large medical libraries and should prove valuable to all persons interested in the subject.

*Headache*. By Louis G. Moench M.D. assistant clinical professor, University of Utah School of Medicine and internist, Salt Lake Clinic, Salt Lake City. 8°, cloth, 207 pp., with 58 illustrations. Chicago: Year Book Publishers Incorporated, 1947. \$3.50.

The researches of recent years have advanced greatly the knowledge of the troublesome symptom of headache. Dr. Moench has brought together in one volume for ready reference the latest ideas on the subject. He classifies the material according to the origin of the symptom: pathological anatomy and physiology followed by headache from intracranial disease, spinal puncture and ventriculography, cranial nerve neuralgias, headaches of ocular and nasal origin from disease in the neck and from systemic disorders, histamine headaches, migraines and headaches of emotional origin. A list of references is appended to each chapter and a good index concludes the volume. The material is well organized. The printing is well done with a good type on good paper. The book is recommended for all medical libraries and should prove useful to the general practitioner for whom it is written.

*Neutron Effects on Animals*. By the staff of the Biochemical Research Foundation. Dr. Ellice McDonald, director, Newark, Delaware. 8° cloth, 198 pp. Baltimore: Williams and Wilkins Company 1947. \$3.00.

The cyclotron employed in these researches was specially constructed for biochemical and biologic study. During an investigation on the blood for the Manhattan District it ran continuously for more than a year without missing a day. For the past eight years the staff of the Foundation has been studying the forces and material produced by the machine. The twenty papers presented in this volume represent the preliminary studies on the effects of neutrons on body tissues and fluids of the lower animals. The volume is well published in every way and its price is reasonable. This is a book in a new field and is recommended for all medical libraries.

*Morphologic Hematology* Special issue No 1 of *Blood, the Journal of Hematology* William Dameshek, M.D., editor-in-chief 4°, cloth, 200 pp New York Grune and Stratton, 1947 \$4.75

In this symposium twenty-six recognized authorities have combined in a discussion of the physiologic and pathologic morphology of the blood in man and in animals. The volume is well published in every way and should be in all medical libraries.

*Training in Clinical Psychology* Transactions of the first conference, March 27, 28, 1947, New York City 8°, paper, 88 pp New York Josiah Macy, Jr., Foundation \$1.50

This small volume presents the various papers read at the conference of specialists held in New York in 1947. The discussions centered on the problems of training in clinical psychology and psychoanalysis. The type, paper and printing are good, but the ring type of binding is not suitable for permanent preservation of valuable material. However, the volume should be in all medical libraries.

*Gifford's Textbook of Ophthalmology* By Francis H. Adler, M.D., professor of ophthalmology, University of Pennsylvania School of Medicine. Fourth edition 8°, cloth, 512 pp, with 310 illustrations Philadelphia W. B. Saunders Company, 1947 \$6.00

This standard textbook has been revised in the light of the original concept of Dr. Gifford. The book is intended primarily for medical students and general practitioners, with emphasis on conditions that they may safely treat themselves. The techniques of refraction and operations have been condensed considerably, and surgical procedures have been given a separate chapter. Special emphasis has been placed upon the relation of the eye to general medical and neurologic conditions. The references appended to each chapter have been confined to those in the English language. A good index concludes the volume. The text is well organized, and the publishing well done in every way. The book should prove useful to the general practitioner.

*Pharmacology, Therapeutics and Prescription Writing For students and practitioners* By Walter Arthur Bastedo, Ph.D., Ph.M. (Hon.), M.D., Sc.D. (Hon.), consulting physician, St. Luke's Hospital, New York, St. Vincent's Hospital, Staten Island and the Staten Island Hospital. Fifth edition 8°, cloth, 840 pp, with 82 illustrations Philadelphia W. B. Saunders Company, 1947 \$8.50

This new edition of a standard reference work first published in 1913 has been completely rewritten. This has been made necessary by the therapeutic advances since the printing of the previous edition in 1937. Parenteral administration is given due consideration. Material has been added on the amino acids, blood fractions, coagulants and anticoagulants, heparin, dicumarol, curarc, snake venoms, folic acid, rutin, thiouracil, sulfonamides, penicillin, streptomycin, demerol, metopon, the cardiac glycosides, the antimalarials, the mercury diuretics and the BAL treatment of poisoning by arsenic, gold and other substances. Details of the modern treatment of shock and of anemias, and syphilis are given. Carbon monoxide, carbon disulfide, the cyanides and lead are discussed, not as remedies but as serious poisons. A comprehensive index concludes the volume. The book is well published in every way, and a light paper is used, making a light volume for its size. It is recommended as a reference work for all medical libraries and for physicians.

*Edinburgh Post-Graduate Lectures in Medicine* Volume III 8°, cloth, 587 pp Edinburgh Oliver and Boyd, 1946 15 sh

This is the third of a series of volumes presenting in inexpensive editions the postgraduate lectures delivered in the Royal Infirmary of Edinburgh. This series comprises thirty lectures delivered during the season 1942-1943 by specialists and covers the whole field of medicine, including surgery. The volume is well published and should be in all medical libraries. It is an outstanding example of this type of publication.

*Fundamentals of Immunology* By William C. Boyd, M.D., associate professor of biochemistry, Boston University School of Medicine. Second edition 8°, cloth, 503 pp, with 50 illustrations and 66 tables New York Interscience Publishers, Incorporated, 1947 \$6.00

This textbook has been written primarily for students and research workers. First published in 1943, the book has been completely revised within the scope of its objective of presenting basic facts and not exhaustive discussions. Each chapter is documented with a list of references. The material is well organized, and the book is well published in every way and printed on a soft paper pleasing to the eye. It is an ideal textbook.

*Developmental Diagnosis Normal and abnormal child development clinical methods and pediatric complications* By Arnold Gesell, M.D., and Catherine S. Amatruda, M.D. Second edition, revised and enlarged 8°, cloth, 496 pp, with 21 illustrations New York Paul B. Hoeber, Incorporated, 1947 \$7.50

Dr. Gesell has thoroughly revised this new edition of his work, which was first published in 1941. A number of additional case studies have been incorporated in the text. They include diagnostic problems involved in amentia, convulsive disorders, cerebral injuries, blindness, deafness, infantile aphasia, congenital anomalies and prematurity. Material has been added on prenatal rubella, the Rh factor, retrolental fibroplasia and electroencephalography, as well as sections on behavior growth and hygiene of the fetal infant and on the physician's role in the problem of child adoption. The literature has been brought up to date. A good index completes the volume. The book is well published in every way. It is recommended for all medical libraries and should prove valuable to all physicians dealing with young children.

*Handbook of Diagnosis and Treatment of Venereal Diseases* By A. E. W. McLachlan, M.D., Ch.B. (Edin.), D.P.H., F.R.S. (Edin.), consultant in venereal diseases, City and County of Bristol, lecturer in venereal diseases, University of Bristol, and honorary consultant in venereal diseases, Bristol General Hospital. Third edition 12°, cloth, 375 pp, with 160 illustrations, 20 in color Baltimore Williams and Wilkins Company, 1947 \$5.00

The third edition of this British handbook has been revised to include the knowledge gained of the value of penicillin therapy. The soundness of the text is evidenced by the need of three editions in four years. The book reflects the best British opinions and experience. Manufactured in Great Britain, it is well printed with a good, large, legible type. Primarily intended for undergraduate and postgraduate students, it should prove useful to the general practitioner.

*Fundamentals of Psychiatry* By Edward A. Strecker, M.D., Sc.D., LL.D., Litt.D., professor of psychiatry and chairman of the department, Undergraduate and Graduate School of Medicine, University of Pennsylvania, psychiatrist to the Pennsylvania, Philadelphia and Germantown hospitals, consultant and chief-in-service, Institute of Pennsylvania Hospital, and consultant to the Surgeon General, United States Navy. Fourth edition 12°, cloth, 325 pp, with 21 illustrations Philadelphia J. B. Lippincott Company, 1947 \$4.00

This manual first published in 1942 has been thoroughly revised in this fourth edition. Much material has been added including a chapter on psychosomatic psychiatry. Two suggested nomenclatures have been included in the text. The soundness of the compend is evidenced by the demand for four editions since the publication of the first in 1942.

*Practical Clinical Psychiatry* By Edward A. Strecker, A.M., M.D., Sc.D., Litt.D., LL.D., professor of psychiatry, University of Pennsylvania, Franklin G. Ebaugh, A.B., M.D., professor of psychiatry, University of Colorado School of Medicine, and director, Colorado Psychopathic Hospital, and Jack R. Ewalt, M.D., professor of neuropsychiatry and director, Galveston State Psychopathic Hospital, University of Texas Medical Branch. Section on Psychopathologic

*Problems of Childhood* By Leo Kanner M.D. associate professor of psychiatry, Johns Hopkins University School of Medicine. Sixth edition. 8° cloth 476 pp with 35 illustrations and 12 tables. Philadelphia: Blakiston Company 1947. \$5.00.

This authoritative textbook first published in 1925 and last revised in 1940 has again been revised to the light of the extensive knowledge of psychiatry gained during the years of World War II. This edition includes both the military and standard nomenclatures. An extensive bibliography is appended to each main section and a good index concludes the volume. The book is well published in every way. It is recommended for all medical and mental libraries and to all physicians interested in psychiatry.

*Public Health Law* By James A. Tobey, Dr. P.H. 1.L.D. Third edition. 419 pp. New York: Commonwealth Fund 1947. \$4.50.

Much material has been added to this new edition of a standard reference monograph. Approximately two hundred and fifty new decisions of courts of last resort on various aspects of public health law have been referred to or abstracted; numerous alterations in governmental organization and administration have been noted and important legislative trends have been reported. The text is well printed with a good legible type on soft, light paper. A general index and one of cases conclude the volume. The book is recommended for all medical, public health and law libraries and should prove valuable to public health officers and lawyers.

*Communicable Diseases* By Franklin H. Top, M.D. M.P.H. medical director, Herman Kiefer Hospital, clinical professor of preventive medicine and public health, Wayne University College of Medicine and extramural lecturer on infectious diseases and epidemiology, School of Public Health, University of Michigan. Second edition. 8° cloth 992 pp with 95 illustrations and 13 color plates. St. Louis: C.V. Mosby Company 1947. \$8.50.

Dr. Top and his collaborators have revised all chapters of this standard work first published in 1941. Fourteen new chapters have been added on various diseases and the number of collaborators has been increased to twenty. The chapters on influenza, malaria and rickettsial diseases have been completely rewritten. Many illustrations in black and white and in color have been added. A bibliography is appended to each chapter. The appendices present morbidity tables and a glossary of medical words. A good index concludes the volume. The book is recommended for all medical libraries and to all physicians interested in communicable diseases.

*A Textbook of Clinical Neurology. With an introduction to the history of neurology.* By Israel S. Wechsler M.D. clinical professor of neurology, Columbia University neurologist, Mount Sinai Hospital and consulting neurologist, Montefiore Hospital and Rockland State Hospital, New York. Sixth edition. 8° cloth 829 pp with 162 illustrations. Philadelphia: W.B. Saunders Company 1947. \$8.50.

The first edition of this standard textbook was published in 1927 and the previous revision was made in 1943. This sixth edition has been revised to bring the text up to date. Material has been added and the chapter on psychometric tests has been completely rewritten and its name changed to Psychologic Diagnosis. The list of references attached to each chapter has been revised by the inclusion of new titles and the deletion of obsolete references. A comprehensive index concludes the volume. The book is well published in every way in the characteristic style of the publisher. It is recommended for all medical libraries and to all persons interested in neurology.

*The Rotunda Hospital 1745-1945* By O'Donell T.D. Browne M.B. M.A. M.A.O. (Univ. Dublin), F.R.C.P. (I), F.R.C.O.G. King's professor of midwifery, Trinity College, Dublin; gynecologist, Sir Patrick Dun's Monksdown and Stewarts Hospitals, Dublin. 4° cloth 296 pp with 44 plates and a chart. Baltimore: Williams and Wilkins Company 1947. \$11.00.

In this volume is portrayed the history of the Rotunda Hospital of Dublin, Ireland. The book is divided into six

parts. The first two are devoted to a chronologic history of this famous obstetric hospital and the Dublin School of Midwifery. The succeeding chapters discuss the struggle against puerperal fever, operative midwifery, anesthesia, gynecology and eclampsia. In the section on puerperal fever the part Oliver Wendell Holmes of Boston played in the prevention of this disease is fairly and impartially discussed. The volume is well published in every way. It is printed with a good large type of soft paper. The book should be in all medical history collections.

*Endocrinology of Neoplastic Diseases. A symposium by eighteen authors.* 8° cloth 392 pp. New York: Oxford University Press 1947. \$11.00.

This symposium, originally published in *Surveys* in 1944, has been revised and brought up to date as of 1946. The various papers discuss the endocrinologic aspects of tumors of the pituitary body, ovary, uterus, breast, prostate, testicle, adrenal glands, thyroid and parathyroid glands, pineal gland and the pancreas and present the latest information on the various topics. A long bibliography is appended to each chapter. The printing is well done with a good type set on a half-filled paper not essential for this type of book. The price seems excessive for the volume. The work is recommended as a reference text for medical libraries and should prove valuable to physicians interested in the subject.

*Clinical Pediatrics* By I. Newton Kugelmann M.D. Ph.D. S.D. attending pediatrician, Downtown Hospital, Pan American Clinic, Lynn Memorial Hospital, Monmouth Memorial Hospital and Muhlenberg Hospital, New Jersey. Second edition. 8° cloth 409 pp. New York: Oxford University Press 1947. \$4.00.

The purpose of this epitome is to emphasize the determining features of pediatric problems as a basis for more detailed study of the individual child in health and disease. The material is arranged to an outline manner and divided into eighteen parts based on an anatomic classification. The volume is well printed and should prove useful to physicians interested in pediatrics and should be valuable in differential diagnosis.

*Essentials of Pharmacology* By Frances K. Oldham M.Sc. Ph.D. research associate in pharmacology, University of Chicago; F.L. Kelsey, Ph.D. associate professor of pharmacology, University of Chicago; and E.M. K. Gelling, Ph.D., M.D. Frank P. Hixon Distinguished Service Professor and chairman of the Department of Pharmacology, University of Chicago. 8° cloth 440 pp. Philadelphia: J.B. Lippincott Company 1947. \$5.00.

This manual is intended as an introductory text in pharmacology in which the general principles of the subject are stressed. The text is divided into three parts: general principles, functional drugs and chemotherapeutic agents. To each chapter is appended a selected list of references for further reading. A good index concludes the volume. The text printed on a good soft paper should prove useful to students and others desiring a good compendium of the subject.

*Endogenous Endocrinology: Including the causal cure of cancer compendium.* By Dr. Jules Samuels. 8° cloth 539 pp with 30 illustrations. Amsterdam: Holland-Holdert and Company 1947. \$10.00.

The author is contemplating the publication of a large five-volume treatise on endogenous endocrinology and is issuing this volume as a preliminary compendium to his treatise. He outlines his theory of hypophyseal dysfunction and of its relation to various diseases. He believes that restoration of the balance of the pituitary gland may arrest tumor growth. He claims that after his method of treatment a number of patients have survived for five to seven years and have continued to enjoy good health. The first part of the book discusses the subject in general and the use of the short wave current to treatment. The second part considers the various diseases susceptible to treatment, with a long section on proliferation diseases including cancer. The book is well printed on good paper but is unduly bulky for its size. All physicians interested in cancer should have access to this volume.

WHETHER we like it or not, the social and economic problems of medicine today must be faced, and by constructive efforts we must attempt their solution. As physicians, we are prone to keep away from politics and perhaps properly so. At least, we have not to any degree played politics" in the usually accepted sense of the word. I believe that the time has come when this society should take a more active part as a society, in the solution of these urgent problems. However much we may do as individuals, I believe that we do not use to full advantage the collective experience and ideas of the members of the society, who represent so well the art and science of surgery in New England. I believe that the recommendations of this society on such vexing problems as nursing service, hospital administration, costs of surgical care and training of surgeons can and should carry a greater weight. We are in a strategic position, for we represent, as no similar group does a cross-section of New England as a whole. We are familiar with the complexities of these problems in many widely differing localities.

These problems cannot be solved by an attempt to apply to New England as a whole the ideas that may emanate from one central body of the United States. Just as certainly, we cannot apply with good effect the methods of solution in northern New England that may be effective in meeting the needs of greater Boston. The remedies must be based on the needs of the local community, and the local conditions are known best by those who live in that community. The mere knowledge of the local needs, however, is not enough. These needs must be integrated with the over-all picture.

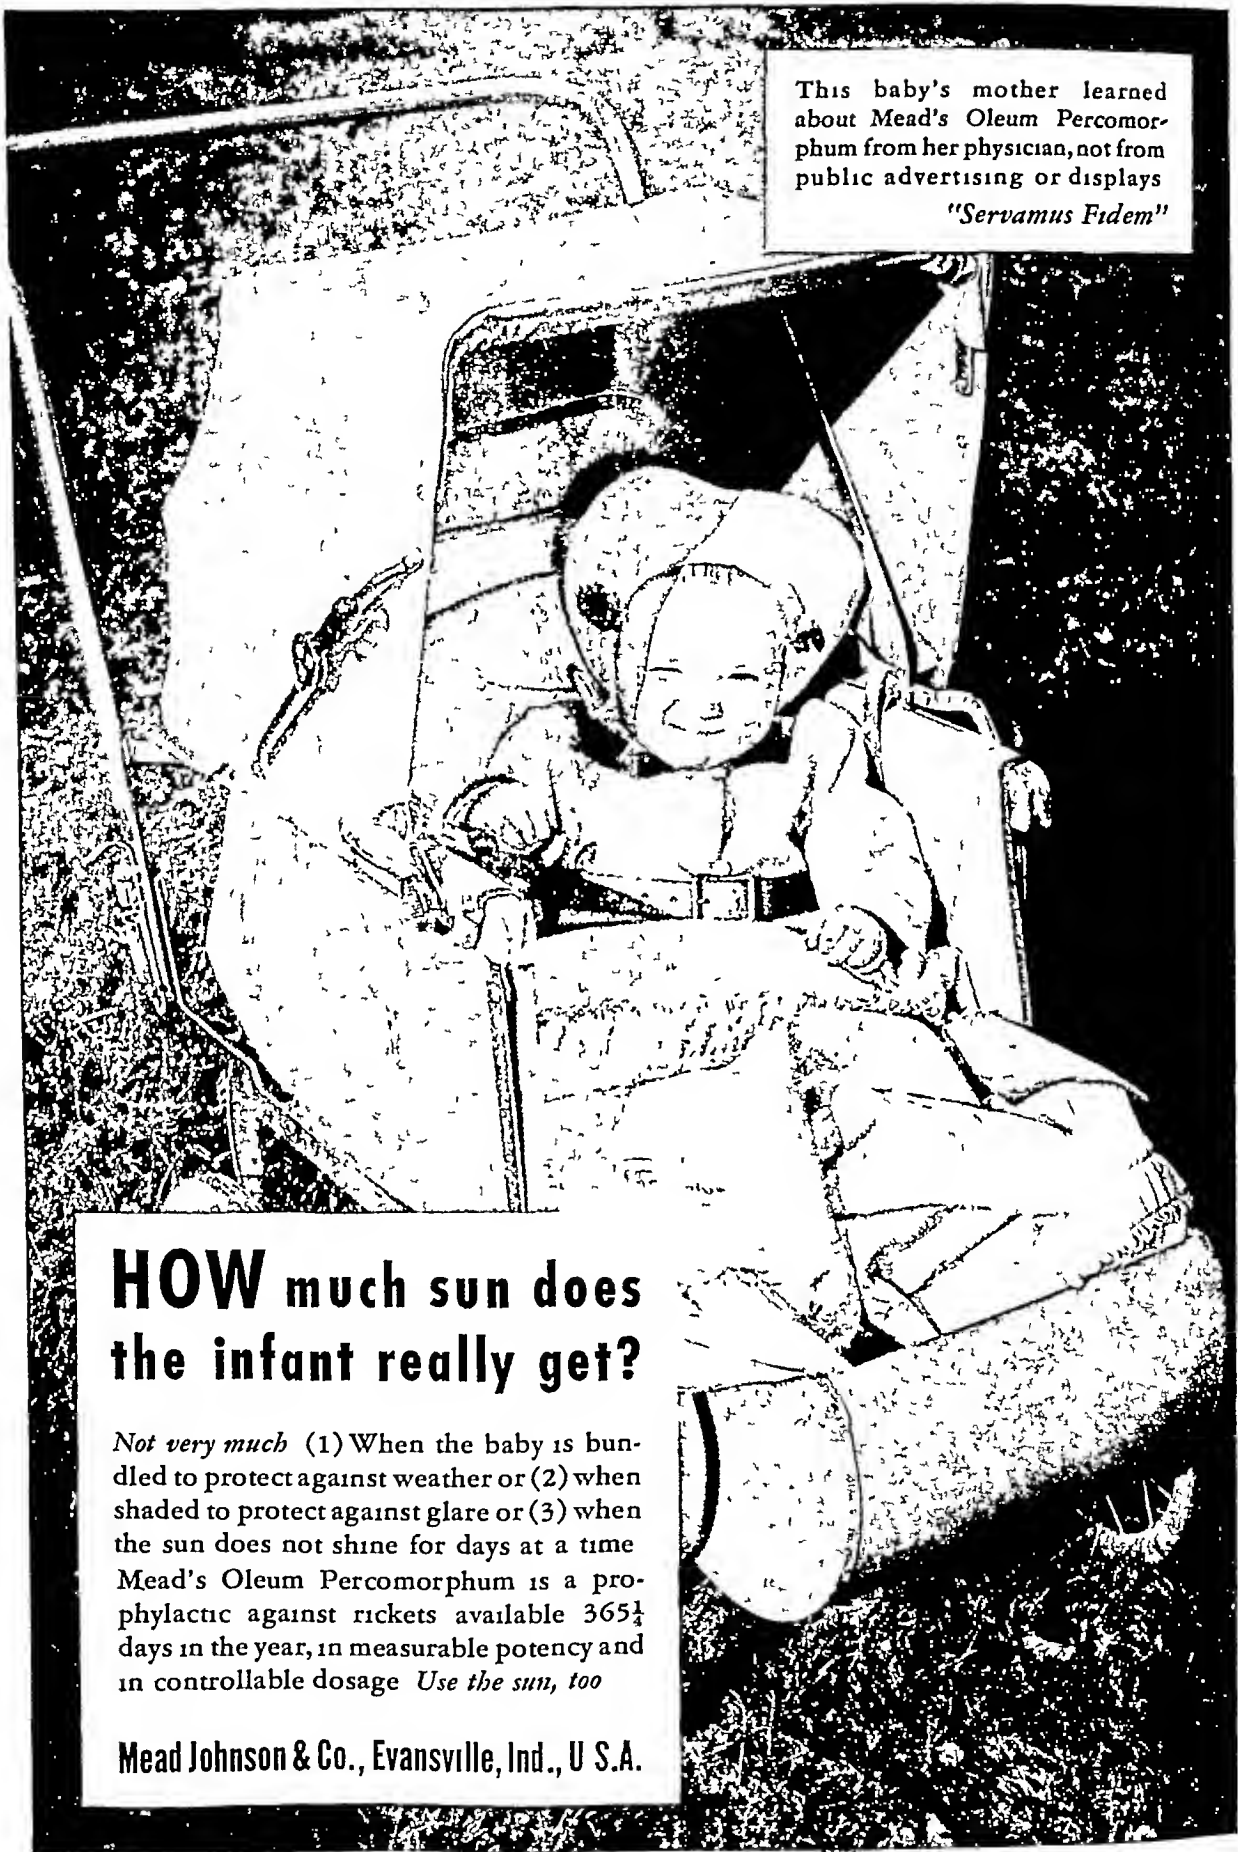

A commander-in-chief must have a sound, tactical and strategic plan, which must be carried out by the division, battalion or even company commander. The methods of putting the plan into effect, however, by commanders of the lower echelons must be co-ordinated with the over all campaign, or

chaos will result. I do not know which is worse, a good plan coming from a centralized headquarters that does not permit of variation to meet the local needs or a good local plan that takes little or no account of the problem as a whole throughout the country.

The New England Surgical Society is particularly well equipped to do constructive thinking and co-ordinate local with general plans. In surgical training for example, other urgent questions such as the nursing situation, the changing problems in hospital administration and, in particular, professional fees and the cost of surgical illness are important, and we must take our part in solving them. But the training of surgeons is a large enough subject to warrant its being considered alone although any solution must include consideration of the others—notably, the costs of surgical illness. In the New England States, as perhaps in no other part of the country of comparable geographical size, we have many, if not all of the conditions that affect the training of a surgeon and his later surgical career and we have a cross section of this subject as it applies to the country as a whole. We have a large metropolitan area, Boston, which has not one but three Class A medical schools, all of which are endeavoring to meet this problem—the training of the surgeon. In New Haven, Burlington and Hanover are single medical schools, and the problems in these localities may be quite different in their practical solution. We have our larger industrial centers, and we have our smaller urban communities and our rural districts. The combined individual opinion of members of this society, therefore, should carry great weight. We cannot solve the problems by meeting the needs of the teaching centers alone. By the same token, what is applicable to Bridgeport or Salem may not be suitable for Bangor or St. Albans, nor can the needs of the rural communities be met by methods applicable to the cities, whether or not they have medical schools. I believe that the rules of the American Board of Surgery must be made more flexible and that they should be influenced by the

## PRESIDENTIAL ADDRESS\*

THOMAS H. LANMAN, M.D.†

BOSTON

WHETHER we like it or not, the social and economic problems of medicine today must be faced, and by constructive efforts we must attempt their solution. As physicians, we are prone to keep away from politics and perhaps properly so. At least, we have not to any degree played politics in the usually accepted sense of the word. I believe that the time has come when this society should take a more active part, as a society, in the solution of these urgent problems. However much we may do as individuals, I believe that we do not use to full advantage the collective experience and ideas of the members of the society who represent so well the art and science of surgery in New England. I believe that the recommendations of this society on such vexing problems as nursing service, hospital administration, costs of surgical care and training of surgeons can and should carry a greater weight. We are in a strategic position for we represent, as no similar group does, a cross-section of New England as a whole. We are familiar with the complexities of these problems in many widely differing localities.

These problems cannot be solved by an attempt to apply to New England as a whole the ideas that may emanate from one central body of the United States. Just as certainly, we cannot apply with good effect the methods of solution in northern New England that may be effective in meeting the needs of greater Boston. The remedies must be based on the needs of the local community, and the local conditions are known best by those who live in that community. The mere knowledge of the local needs, however, is not enough. These needs must be integrated with the over-all picture.

A commander-in-chief must have a sound, tactical and strategic plan, which must be carried out by the division, battalion or even company commander. The methods of putting the plan into effect, however, by commanders of the lower echelons must be co-ordinated with the over-all campaign, or

chaos will result. I do not know which is worse, a good plan coming from a centralized headquarters that does not permit of variation to meet the local needs or a good local plan that takes little or no account of the problem as a whole throughout the country.

The New England Surgical Society is particularly well equipped to do constructive thinking and co-ordinate local with general plans. In surgical training for example, other urgent questions such as the nursing situation, the changing problems in hospital administration and in particular, professional fees and the cost of surgical illness are important, and we must take our part in solving them. But the training of surgeons is a large enough subject to warrant its being considered alone, although any solution must include consideration of the others—notably the costs of surgical illness. In the New England States, as perhaps in no other part of the country of comparable geographical size, we have many if not all, of the conditions that affect the training of a surgeon and his later surgical career, and we have a cross section of this subject as it applies to the country as a whole. We have a large metropolitan area, Boston, which has not one but three Class A medical schools all of which are endeavoring to meet this problem—the training of the surgeon. In New Haven, Burlington and Hanover are single medical schools, and the problems in these localities may be quite different in their practical solution. We have our larger industrial centers, and we have our smaller urban communities and our rural districts. The combined individual opinion of members of this society, therefore, should carry great weight. We cannot solve the problems by meeting the needs of the teaching centers alone. By the same token, what is applicable to Bridgeport or Salem may not be suitable for Bangor or St. Albans, nor can the needs of the rural communities be met by methods applicable to the cities, whether or not they have medical schools. I believe that the rules of the American Board of Surgery must be made more flexible and that they should be influenced by the

† Chief, Department of Surgery, Harvard Medical School, Surgeon, Children's Hospital.

sound and collective opinion of the members of this society. We should furnish our representatives on the various boards with a clearer picture of the varying needs in the various communities.

This year, the Program Committee is devoting a larger part of its attention to papers that deal with the broader aspects of surgery. It is our hope to find out, if possible, what this society might do as a society in further advancing the purpose of various agencies, political and medical, that have been organized on a national basis. Our members have had a prominent part in the organization and the aims of the American Board of Surgery. Our members have also played an important part in the American College of Surgeons, the National Cancer Society and similar groups. I think it should continue to do so and should make its considered opinions as a society heard and felt in the recommendations of these bodies. Already, conditions are quite different, as far as the surgical training program is concerned, than they were when the Board of Surgery was organized. The war and its political, social and economic sequelae have disrupted surgical training to a considerable degree. In addition, the practice of surgery is going through tremendous advances and changes—I use the two words purposely, for I do not consider *all* the present changes advances.

It is certain that the minimum requirements before a candidate can be certified by the American Board of Surgery are sound in principle, but I believe they need a greater flexibility in their application. How many of our members meet the present requirements of the American Board of Surgery, as far as their formal training in length of internships and residencies is concerned? I know that I do not.

In his address as president of the American Orthopedic Society, in June, 1946, Dr J. Albert Key,<sup>1</sup> of St. Louis, stated

Due to the unswerving devotion to duty of the Membership Committees, our American Orthopedic Association comprises a group of orthopedic surgeons whose ability cannot be questioned, and yet, I doubt if 10 per cent of our present membership could meet the present training requirements. It is thus evident that it must be possible for one to become proficient in orthopedic surgery by other routes. I wonder if we are not making a grave mistake in our attempt to regiment the training of orthopedic surgery. To limit future orthopedic surgeons to those of our young medical graduates who can be forced into a mold is to exclude many whose qualifications justly entitle them to certification and whose abilities as orthopedic surgeons would be of great value.

This statement from one of the leading orthopedic surgeons in America is significant, and it is equally significant in its application to the training of the general surgeon. (Although there is some difference of opinion regarding the relative importance of the surgeon and the orthopedist, there is no question that both should be well trained.) We have only to read the list of members of this society to appreciate that many competent, out-

standing surgeons have reached the enviable positions that they hold without going through the present formal requirements of the American Board of Surgery. No one should misinterpret these remarks and feel that I, in any way, advocate lowering the ideals for the training of a surgeon. But I do agree with Dr. Key that we are in danger by regimentation, of excluding from certification many men whose talents and abilities justify such recognition as surgeons.

The following paragraph of a letter (recently published in the *New England Journal of Medicine*, from a young surgeon now in the course of receiving his training in Boston for the American Board of Surgery is quoted as being of interest:

As the ward beds are encroached on by private and semi-private cases, there will be fewer and fewer cases under the care of the house staff. Coincidentally, and stimulated by the requirements of the American College of Surgeons and American Board of Surgery, more and more men desire a longer training period. Thus, the problem of adequate training for the young surgeon becomes increasingly difficult. No one will deny that increased training is a desirable thing, but where are the beds to train so many for so long? That would be difficult to answer in any event, but with the increasing shortage of ward beds it will become even more so. The answer to these questions must be forthcoming soon.

As this young correspondent points out, the so-called "ward beds" in the teaching hospitals are becoming fewer because of certain insurance plans such as the Blue Cross, as well as other economic factors. As a result, the opportunities for the proper surgical training of residents—particularly the actual operative work done by the house staff—are proportionately poorer. In passing, it is rather interesting to note his phraseology, "ward beds are encroached on by private cases." This is certainly a different point of view from that held by those of us who were trained in the era when a private patient was unheard of in the institutions in which we served as interns.

Another side of this question will become apparent to the young surgeon when he completes his training, and I quote in substance the editorial reply to the letter referred to:

There will be a further problem confronting the young surgeons who have completed their residencies in these institutions where, under excellent supervision by the chief, 80 to 90 per cent of the ward patients are properly cared for by the house staff, but who, unfortunately for themselves and for the communities in which they are needed, elect to remain in the large teaching hospitals as junior attending surgeons. In such institutions, these men are placed on service for periods of several months during the year, but if they are fair to the resident staff, by "handing down" the bulk of the operative work (as others did for them when they were of the house staff) they get little return in practical operative

experience from the amount of time that they devote to the hospital. On the other hand, the young surgeon who has had four or five years of active, well supervised training may fare little better if he goes to a community hospital, unless he is fortunate or wise enough to choose a locality in which there is real need for a surgeon.

These trends appear to be inevitable, and it is certain that the present system of postgraduate surgical training does not suffice and, what is of even greater importance in my opinion, it has now a tendency to disrupt an equitable distribution of surgeons. Too few opportunities are available for the present requirements in postgraduate surgical training, furthermore, too many well trained young surgeons remain in the large teaching centers, partly because little incentive is offered for moving to smaller communities. There are several ways of relieving this situation, in particular, a more widespread adoption of the fellowship or preceptorship as a method of surgical training is desirable, and with this, the development of community hospitals as teaching centers. It is here that our society can be of great assistance. Other schemes will undoubtedly be devised as the necessity arises. Certainly, efforts should be made to meet the demand not only for providing the necessary number of well trained surgeons but also for their equitable distribution throughout the country.

I suggest that some method be devised whereby the collective opinion of members of this society be more accurately obtained and that our recommendations be, in some way, officially brought to the attention of the governing bodies of societies of national scope. This year, we have a paper by Dr Harvey about the American Board of Surgery. We shall also hear something of the surgical problems in smaller communities, and a report on "detection clinics" in their statewide and national scope. All these have a bearing on the present problems. It may be worth while for our executive committee to consider having even more time devoted each year to a discussion of these questions, and to accomplish this it might be desirable to have

a longer annual meeting. Another suggestion is to have a second meeting during the year at which such problems could be discussed, leaving the purely scientific papers for the annual meeting. One hesitates to suggest the formation of still another committee, but perhaps this is the best way to study these problems adequately. Surely they are important enough to justify active and practical steps to forward their solution. Concerning the problem of the training of surgeons, I suggest that although certification or some similar tangible recognition of the adequacy of a man's training is desirable, the requirements must be flexible enough to meet the varying needs of a representative geographical area such as New England. Rules for certification that are too rigid may defeat their purpose. In addition, it should not be forgotten that whereas an examination may cover the tangible technical ability of the candidate, even though he passes with honor, he may be a dangerous man in his community if he does not possess the intangible qualities of character that cannot be determined by examination alone. These intangibles are better apparent to those who know the candidate by personal contact. It is here that the preceptorship has its unique advantage, and I suggest that this society is in a strong position to encourage its wider use and to know how far such preceptorships can be usefully employed to meet the varying needs of New England — not only for Board certification but also as a means of attracting men of high caliber to practice surgery where they are needed. Above all this society should make every effort both to provide adequate training for men of good character and to see that these men have adequate opportunities to practice where they are most needed. Today, an equitable distribution of well trained surgeons is even more important than their number.

## ROENTGENOGRAPHIC STUDIES OF THE GASTROINTESTINAL TRACT FOLLOWING SECTION OF THE VAGUS NERVES FOR PEPTIC ULCER\*

MAX RITVO, M D,† AND IRVING A SHAUFFER, M D ‡

BOSTON

THERE is widespread interest in the surgical treatment of chronic, intractable peptic ulcer by section of the vagus nerves. Dragstedt and his co-workers<sup>1</sup> in Chicago were the first to employ the procedure systematically, and since their publication of the results of supradiaphragmatic vagus resection in 2 patients in 1943 they have reported progressively larger series of cases, which reached a total of 90 in 1946.<sup>1,2</sup> Moore<sup>3</sup> has recorded 40 cases. Grimson and Ruffin<sup>4-6</sup> have discussed a series of 57 cases. Previous reports of the findings in transthoracic, bilateral vagus-nerve resection have described changes in size, shape, motility and emptying of the stomach following operation. The findings have varied in different series and from time to time in the same series. Carlson,<sup>7</sup> in 1923, noted that bilateral vagotomy resulted in decrease of tone and diminution in the number of hunger pangs although the gastric contractions remained apparently normal in amplitude. In 1926 McCrea<sup>8</sup> stated that the motor activity of the stomach was not altered by unilateral vagotomy and, except for a decrease in initial emptying time, was not appreciably influenced by section of both vagus nerves. Hartzel,<sup>9</sup> in experimental work with dogs in 1929, demonstrated that section of both vagus nerves decreased the acidity of the gastric contents. In addition he noted a marked increase in initial and a slight increase in final emptying time of the stomach with no gastric dilatation. On post-mortem examinations of 2 dogs, seven and thirty-five days, respectively, after vagotomy, he found no abnormalities in the stomach. In 1935 Ferguson<sup>10</sup> described decreased gastric tone and delayed initial emptying time after sectioning the vagi of 10 monkeys. An interesting feature of this work was that cardiospasm occurred postoperatively in all the animals whether the vagi were sectioned in the cervical region or transabdominally. In 1938 Winkelstein and Berg,<sup>11</sup> who found that anterior vagotomy and partial gastrectomy produced achlorhydria, advocated anterior subphrenic vagotomy with gastroenterostomy for duodenal ulcers to prevent the development of jejunal ulcer. Weinstein et al.,<sup>12</sup> in a comprehensive review of the literature in 1944, came to the conclusion that vagotomy was only partially successful in the treatment of peptic ulcer, since delay in emptying of the stomach was the sole result achieved. In a series of 15 cases

Dragstedt<sup>13</sup> indicated that 3 required subsequent gastroenterostomy after vagotomy because of obstruction and delayed gastric emptying. One patient developed acute dilatation of the stomach eight weeks postoperatively, and 2 had gastric atony during the first week or two after operation. In the remaining cases peristalsis, position and tonus of the stomach appeared to be normal, and the esophagus and intestines revealed no abnormalities on roentgenographic study.<sup>14</sup> Later observations by this group<sup>15,16</sup> showed that there was a decrease of gastric tonus subsequent to the surgery. By using balloons, they found that hunger contractions remained normal in duration but were diminished in amplitude. Although decreased gastric motility was found in all cases, no decrease occurred in intestinal motility.

Moore and his associates<sup>17</sup> described definite changes in gastric function after vagus resection. There was delay in the initial emptying and prolongation of final emptying. The former was considered to be normally one half to one and a half minutes, and the latter about two and a half hours. By the use of electronic apparatus, the authors found postoperative absence of large gastric contractions and decrease in peristaltic activity. Eight months postoperatively they noted a return to normal in the amplitude of gastric contraction but a persistence of abnormality of pattern. In a later paper Moore<sup>18</sup> stated that gastric emptying returned to normal after six to eight months, with disappearance of all motility changes in that time. Subsequently, he<sup>3</sup> noted that gastric motility approached normal levels at the end of a year. The gastric atony observed roentgenoscopically disappeared in three to nine months, although delay in emptying persisted in some cases. Changes distal to the pylorus were indefinite and variable. Baronofsky et al.,<sup>19</sup> in 1946, found marked atony and dilatation of the stomach after vagus resection. Grimson and Ruffin<sup>4,5</sup> reported a series of 28 patients in 1946 and described marked delay in emptying, moderate dilatation of the stomach and markedly decreased or absent peristalsis. If gastroenterostomy or gastric resection had been performed previously, the above changes did not occur. Six hour residues of 90 to 100 per cent were present in 10 cases, with lesser degrees of delay in emptying in 10 others. Seven of the remaining 8 patients had had previous gastric operations. Three cases required operation because of retention, and the stomach appeared to empty well after sev-

‡Resident physician, Department of Radiology, Boston City Hospital.

eral months. Later, Smith, Ruffin and Baylin<sup>8</sup> reported a series of 50 cases in which, after operation, there was moderate or marked dilatation of the stomach, with absent or slow, arrhythmical peristalsis. Objective healing of peptic ulcers occurred in several weeks or a few months. Observations after three to twenty-seven months revealed that in no case had the stomach returned

with chronic peptic ulcer have been performed at the Boston City Hospital. Thirty were men, and 3 women. The ages ranged from twenty-one to fifty-seven, 4 patients being twenty-one to thirty, 9 thirty-one to forty, 8 forty-one to fifty, and 2 fifty-one to fifty-seven years of age. Twenty-one patients had had no gastric surgery prior to the vagus resection. Three had had previous gastro-

FIGURE 1 Roentgenograms in a Fifty-Five Year Old Man with a History of Duodenal Ulcer of Twenty Years Duration and with Pain That Had Become Intractable to Diet and Other Forms of Medical Therapy After Laparotomy. He Was Entirely Relieved of All Complaints and Was Able to Be on a Normal Diet without Recurrence of Symptoms.

A demonstrates the appearance of the stomach ten days after vagotomy. A roentgenogram taken six hours after the ingestion of an opaque meal shows the stomach to be markedly dilated and atonic with absent peristalsis and with retention of the entire opaque meal in the stomach. Twenty-four-hour observation showed marked enlargement and atonicity of the stomach with about 50 per cent gastric residue, and at forty-eight hours there was approximately 50 per cent retention in the stomach. B shows that the stomach, four months after vagotomy, was normal in size and atonic with very sluggish peristalsis — the film taken about fifteen minutes after the ingestion of the opaque meal shows the duodenum contracted and irregular in outline with small amounts of the opaque material in the upper loops of jejunum, indicating that emptying of the stomach is taking place. C which demonstrates a roentgenogram taken six hours after that illustrated in B, shows only a small amount of the opaque meal remaining in the stomach. The head of the opaque column is in the terminal ileum, indicating slight hypomotility and the small bowel loops are slightly atonic but otherwise not remarkable.

to normal. Although the changes were less marked in most cases, the increased dilatation and absence of peristalsis persisted in some.

Grimson and his co-workers<sup>20</sup> reported 57 cases in July, 1947, and made the comment that temporary difficulty in swallowing was noted in 20. In 26 patients studied for small-bowel changes, transit through the jejunum was delayed, the caliber usually increased slightly, and the mucosal pattern tended to become coarse. A new phase of investigation must be considered in the work of Machella,<sup>21</sup> Smith, Ruffin and Baylin<sup>8</sup> and Grimson et al.<sup>20</sup> These studies consisted in the use of urecholine (urethane B-methyl choline) to stimulate peristalsis and increase the rate of emptying of the stomach after vagotomy. The effect of the drug persisted for thirty to forty-five minutes.

#### MATERIAL AND METHOD

Since December 1, 1945, bilateral supradiaphragmatic resections of the vagus nerves on 33 patients

enterostomies with persistence of ulcer symptoms. Of 5 patients who had had partial gastrectomies, 3 had developed intractable marginal ulcers, and 2 refractory jejunal ulcers slightly distal to the stoma. In the 21 patients who had had neither gastrectomy nor gastroenterostomy, 20 had chronic duodenal ulcers, with histories of perforation or hemorrhage in some. One of these, a thirty-five-year-old woman, presented an ulcer of the lesser curvature of the stomach.

Each of the patients in our series was examined roentgenographically and fluoroscopically prior to the resection of the vagus nerves and one or more times postoperatively (Fig 1-3). After the operation, roentgenographic studies were made as soon as it was deemed advisable clinically or when the patient was willing to report to the x-ray department. Thirteen patients were first re-examined within one to three weeks after operation, 16 in three to eight weeks, 3 within ten to fourteen weeks, and 1 after twenty-eight weeks had elapsed.

Of these, 6 have not returned for subsequent observations. Re-examinations were carried out at intervals of a few weeks or months in the remainder of this group, the number and frequency of the studies being determined principally by the patient's co-operation in returning despite the fact that all were symptom free. Several were unwilling to lose time from work or were unco-operative for other personal reasons. Twelve of the group were studied twice, 10 were observed three times, 4 returned four times, and 1 was examined on five occasions. One case has been followed for fourteen months,

bowel, but since no significant changes in caliber or mucosal pattern were demonstrated, this practice was discontinued.

#### PATIENTS WITH NO PREVIOUS GASTRIC OPERATION

The first group to be considered comprised 21 patients who had had neither gastrectomy nor gastroenterostomy previously. Fourteen were examined within three weeks after the vagus resections had been performed, all showed dilatation and atonicity of the stomach. In 5 cases the stomach was markedly dilated, 8 patients presented gastric

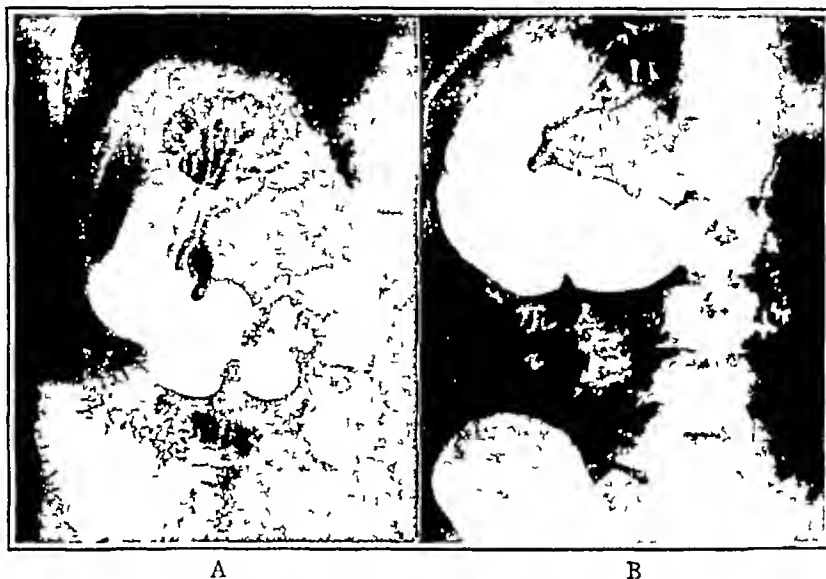

FIGURE 2 *Roentgenograms in a Thirty-Five-Year-Old Woman with a History of Ulcer of Four Years' Duration Whose Response to Medical Therapy Had Been Very Unsatisfactory. After Vagotomy, She Was Promptly Relieved of All Symptoms. Roentgenographic Observations Were Continued at Intervals for Almost a Year and Showed the Stomach to Be Slightly Dilated and Atonic, with Sluggishness or Absence of Peristalsis and Slight Delay in Emptying. There has Been No Recurrence of Pain.*

A, roentgenogram taken before operation, shows the stomach to be hypertonic, with vigorous peristalsis and moderate pylorospasm, the duodenal bulb is markedly irregular and presents an ulcer-crater formation, and there is tenderness over it on fluoroscopic palpation. B, roentgenogram taken twenty-two weeks after vagotomy, demonstrates that the stomach is atonic, with sluggish peristalsis and a widened pylorus, the duodenal bulb shows moderate distention, a constriction across its proximal portion and no ulcer crater or tenderness on fluoroscopic palpation (barium was present in the upper jejunum soon after the ingestion of the opaque meal, and there was no gastric residue at six hours).

3 for eleven months, 5 for seven to ten months, 10 for four to six months, and the remainder for less than four months postoperatively. In each case the esophagus, stomach and duodenum were studied with the barium meal, followed by routine six-hour and twenty-four-hour roentgenograms to determine motility and stasis. If a residue was present in the stomach at the twenty-four-hour observation, the patient was again seen at forty-eight hours and at seventy-two hours or until the stomach was empty. In the first few cases observations were made at hourly intervals after the ingestion of the opaque meal for study of the small

dilatation and atonicity of a lesser degree with enlargement to about twice the normal size. Another showed only slight dilatation. Six patients presented shallow, sluggish, ineffective and arrhythmic peristalsis, in 2 cases there was complete absence of peristalsis. All these patients had retained secretions in the stomach at the time of fluoroscopic study. Fourteen patients showed marked delay in both initial and final gastric emptying. Three had no evidence of any emptying of the opaque material after six hours. Seven had 80 to 95 per cent six-hour gastric residues, and in 4 cases there was 20 to 50 per cent six-hour retention. The marked

delay in the final emptying time is further illustrated by the fact that at the end of twenty-four hours 100 per cent gastric residue was observed in 1 case, 80 per cent in 1, 50 to 60 per cent in 2 and 5 to 15 per cent in 3—a total of 7 cases with twenty-four-hour stasis. At forty-eight hours 1 patient had 80 per cent gastric retention, and another showed 60 per cent gastric residue. The former had a gastroenterostomy performed soon afterward. In 5 cases the initial postoperative examinations were made within three to six weeks after operation. The stomach was dilated to twice the normal size in 3 and was normal in size in 2. All 5 presented sluggish, arrhythmical peristalsis. In this group

showed shallow, sluggish peristalsis, in the other peristalsis was normal. One had no six-hour residue, the second had a trace of the opaque meal retained at six hours, and the last showed 20 per cent gastric residue at the end of three hours.

Seven patients were examined five to six months after operation. In 1 the stomach was normal in size. 4 were found to have only slight dilatation, and in 2 the stomachs were about twice the normal size. Peristalsis was normal in 3 cases and was shallow, sluggish and arrhythmical in the remainder. Gastric residue of approximately 10 per cent at the end of six hours was noted in 5 cases and 25 per cent in 1 case, no six-hour film was

A

B

FIGURE 3 Roentgenograms in a Fifty-One Year-Old Man with a Long History of Recurrent Duodenal Ulcer. Eleven Years Previously He Had Had an Operation after an Acute Perforation Because of Severe Pain. Partial Gastrectomy Was Performed Five Years Later. Until Vagotomy He Had Recurrent Attacks of Pain and Required Hospitalization on Numerous Occasions.

A roentgenogram taken three weeks prior to vagotomy shows a functioning gastrojejunostomy with a large ulcer crater (arrow) in the jejunum in the region of the anastomosis. B roentgenogram taken twenty-one weeks after vagotomy shows that the ulcer crater is no longer demonstrable and that the remaining portion of the stomach is atonic and slightly dilated. Gastric emptying proceeding normally; there was no tenderness over the stoma or the upper jejunal loops, and the patient was free of symptoms and has continued to feel well.

2 patients had 50 to 55 per cent six-hour gastric residues, 1 had 15 per cent residue, and the stomach of 1 was empty at six hours. The fifth patient was not checked at the end of six hours, but after three hours the stomach was about 60 per cent empty. Two patients could not be examined postoperatively until three or four months after operation.

One patient was followed for a month, at the end of which the stomach was twice the normal size, with deep, slow and arrhythmical peristalsis and with a gastric residue of about 80 per cent at the end of six hours. Three patients were observed three to four months after the operation. The stomachs were slightly increased in size. Two

obtained in 1. In 5 patients the initial emptying showed less delay than that immediately after operation but was nevertheless considerably prolonged. In 2 cases the initial emptying was unchanged, being increased as immediately postoperatively. Two patients, seven to eight months after operation, showed stomachs of normal size with sluggish peristalsis. One of these had a 20 per cent six-hour gastric residue, the other had no retention.

In 1 case after an interval of fourteen months the stomach was slightly dilated, with peristalsis of good quality and a six-hour gastric residue of 5 per cent. After eleven months a second patient

presented a stomach that was dilated and atonic, peristalsis was deep and sluggish, and 45 per cent gastric retention was found at the end of six hours. The dilatation and gastric retention appeared to be due to marked constriction of the duodenal bulb. Of the 4 patients in this group whose postoperative roentgenographic findings are not described above, 1 died of a cervical-cord tumor, 1 had had a gastroenterostomy performed at another hospital, 1 has not returned, and the fourth had a subsequent gastroenterostomy, which is discussed below.

#### PATIENTS WITH PREVIOUS GASTROENTEROSTOMY

There were 3 patients who had had gastroenterostomies prior to vagus resection. When studied after the vagotomy, there was slight dilatation of the stomach. One case examined three months postoperatively showed good gastric tone, normal peristalsis and 5 per cent gastric residue at the end of six hours. Another was re-examined one month and three months after the operation and presented similar findings, with 5 per cent gastric stasis at the end of six hours. The third had an unusual progression: the first postoperative examination, after eight months, showed 100 per cent gastric residue at six hours and 50 per cent at twenty-four hours. He returned two months later, when there was complete emptying of the stomach in three hours. He failed to report for further examinations, stating that he had no complaints and did not wish to lose time from work. At both examinations the stomach was slightly dilated, and peristalsis was very sluggish. The gastroenterostomy was not functioning at either observation. As mentioned above, 1 patient had a gastroenterostomy after resection of the vagus nerves because of marked gastric dilatation and retention. Roentgenographic examination five months after this operation revealed 5 per cent gastric residue in the portion of the stomach distal to the stoma. Gastric tone was good, and there was prompt emptying via the stoma.

#### PATIENTS WITH PREVIOUS PARTIAL GASTRECTOMIES

There were 5 patients who had partial gastrectomies and subsequently developed intractable marginal or jejunal ulcers. In each of these the initial postoperative roentgenographic examination was made one to five weeks after operation. All showed dilatation of the stomach, with retained secretions and 10 to 15 per cent gastric residue at six hours. No evidence of ulcer crater was found, nor was there tenderness on fluoroscopic palpation in any of these cases postoperatively. One patient in this group after ten months had a 10 per cent gastric residue, although the greater portion of the stomach had been resected. Five months later 2 patients presented 5 per cent gastric residue and

no dilatation of the stomach. Two at the end of two to three months showed the remaining portion of the stomach still slightly dilated, there was no six-hour residue in 1 case, and 5 per cent in the other. In 1 patient a gastrocolic fistula was found after the vagus resection. Despite an ileosigmoidostomy the fistula persisted when he was last examined three months after the vagus resection.

#### PATIENTS WITH TRANSABDOMINAL VAGUS RESECTION

Also included in our series are 4 cases in which vagus resection had been performed transabdominally. Two patients had partial gastrectomies at that time, 1 had no operation on the stomach, and the last had had a previous partial gastrectomy and subsequently developed a jejunal ulcer. Four weeks after vagotomy, the patient who had had no other operation showed no gastric dilatation, peristalsis was shallow, sluggish and arrhythmical, and there was 40 per cent gastric residue in six hours. At the end of six weeks 1 patient who had had a gastric resection at the time of the vagotomy showed slight dilatation of the gastric remnant, with retained secretions. There was a 5 per cent residue at the end of six hours. The other who had had gastric resection at the time of the vagus section showed no dilatation of the gastric remnant at the end of two months. There was retained secretion in the stomach at the time of the examination, but no six-hour residue was found. The fourth patient, a thirty-year-old man who had had a previous gastric resection with a subsequent jejunal ulcer, was examined one and a half weeks after operation. The esophagus was not remarkable, the gastric remnant was markedly dilated and filled with secretions, and the efferent jejunal loop was dilated. No tenderness was present on fluoroscopic palpation. There was 30 per cent gastric residue at six hours. As he complained of regurgitation, vomiting, and distress, re-examination was carried out a week later. At that time the esophagus presented changes consistent with cardiospasm, with narrowing at the esophageal hiatus, reverse peristalsis and marked delay in the passage of thin and thick barium mixture. The esophageal constriction did not cause complete obstruction, the opaque material gradually entering the stomach in a small stream. Re-examination a week later showed similar changes. The patient was esophagoscoped shortly afterward and was found to have no demonstrable narrowing at the junction of the esophagus and stomach, the instrument passing without difficulty. The condition improved, and he was soon able to swallow without dysphagia. Carlson, in discussing a paper by Grimson,<sup>4</sup> reported the development of temporary esophageal stenosis in 1 case subsequent to trans-thoracic vagus-nerve resection. Similar esophageal change has been reported in Ferguson's<sup>10</sup> study of 10 monkeys. Grimson et al., in July, 1947, reported

difficulty in swallowing observed in 20 cases after supradiaphragmatic vagotomy

#### FURTHER OBSERVATIONS

Tenderness was not present on fluoroscopic palpation, and no ulcer crater was demonstrable postoperatively. The duodenal bulb was not clearly visualized in the early roentgenographic examinations in several cases. This was due to marked delay in the initial emptying time. The duodenal cap in patients with chronic duodenal ulcers showed gradual dilatation and decrease in spasticity within a few weeks in some cases. Gastric stomal and jejunal ulcers disappeared shortly after operation. The small bowel was not remarkable in size or mucosal pattern, the motility was slow, apparently owing to delay in initial gastric emptying because as the emptying time decreased, the motility became normal.

#### SUMMARY

A group of 29 patients with transthoracic section of the vagus nerves and 4 with transabdominal vagus-nerve resection were studied roentgenographically. In the early postoperative stages there was definite gastric dilatation and atonicity in most cases. Sluggish, ineffective and arrhythmical peristalsis or absent peristalsis was associated with the dilatation and atonicity. Emptying times both initial and final, were markedly increased. These changes occurred to a lesser degree in patients with previous gastroenterostomies and in those with partial gastrectomies. Two patients had gastroenterostomies after the vagotomy for dilatation and retention.

Follow-up studies showed a return toward the normal in the above changes within six months to a year. Complete return to normal in all respects was not found in any case, 1 patient having been followed for fourteen months after the operation.

The ulcers healed promptly after operation. This was especially striking in the cases of stomal and jejunal ulcers in the patients with partial gastrectomy.

The postoperative size of the small bowel was not remarkable in any case, the motility was slow

apparently owing to the delay in emptying of the stomach.

One patient developed temporary dysphagia after transabdominal vagus-nerve resection.

We are indebted to Dr William R. Morrison, surgeon in chief, First Surgical Service, Boston City Hospital for his assistance and co-operation in the collection and preparation of the material for this paper.

## MULTIPLE LOCALIZED PLEURAL EFFUSIONS AS A MANIFESTATION OF CONGESTIVE HEART FAILURE\*

### Report of a Case

MICHAEL DIMAIO, M D †

PROVIDENCE, RHODE ISLAND

**E**FFUSION into the general pleural cavity is a frequent manifestation of congestive heart failure. On the other hand, pleural effusion localized in an interlobar space is not a common finding, since only 15 cases have been recorded in the literature.<sup>1-11</sup> Multiple, localized pleural effusions associated with heart failure are apparently even more unusual since no record of this phenomenon has been found in a careful review of the available literature.

Although the case reported below is quite similar, in most respects, to those already reported with a single pleural effusion localized in an interlobar space in congestive heart failure, the multiple effusions encountered are of particular interest and appear to justify a report.

#### CASE REPORT

S McD, a 39-year-old, single man, was admitted to the hospital on December 4, 1946, complaining of swelling of the ankles, cough and shortness of breath. The patient stated that he had been well until 2 months before admission, when he had first noticed swelling of the ankles. This condition continued more or less unchanged until admission. About 1 month before admission he developed a continuous cough, productive of moderate amounts of whitish sputum. At the same time he became increasingly short of breath, and this symptom was aggravated by exertion. Two weeks before admission the abdomen began to swell, the cough became distressing, and the shortness of breath became more marked. Because of the progressive nature of the symptoms he was referred to the hospital.

The patient was said to have had rheumatic fever at 13 years of age, but the details of this illness were not known. However, he had never had any cardiac symptoms. There was nothing in the history to indicate a previous episode of congestive heart failure. In February, 1942, he had been admitted to the hospital because of a fractured patella. At that time, in addition to the injury to the knee, physical examination revealed a blood pressure of 140/80, cardiac enlargement, a marked thrill over the entire precordium, a loud presystolic murmur over the apex and a booming systolic murmur over the aortic area. The lungs and abdomen were normal, and there was no peripheral edema.

In 1942 the patient had been rejected for service in the Army because of heart trouble.

He gave no history of pneumonia or tuberculosis. He had had gonorrhea in early adult life. No history of syphilis was obtained. He had drunk large quantities of beer and whisky during the war years.

The family history was irrelevant.

Physical examination revealed a thin, confused man, who was moderately dyspneic, with slight cyanosis of the lips. He coughed frequently, producing a moderate amount of whitish, frothy sputum. The body weight was 68 kilograms (150 pounds). He was 69 inches in height. The skin was pale and moist from perspiration, it was not icteric. The

veins of the head and neck were markedly engorged and tortuous. The pupils were small, round and regular, the reacted normally to light and accommodation. Examination of the fundi was within normal limits. The trachea was in the midline, and there was no tug. The left anterior portion of the chest was more prominent than the corresponding region on the right. The percussion note over the entire chest was normal. Loud, moist, bubbling rales were audible throughout both lung fields, anteriorly and posteriorly. No thrills or shocks were palpated over the precordium. On percussion the relative area of cardiac dullness was found to be increased, extending approximately 12.0 cm to the left of the midsternal line in the sixth intercostal space and 5 cm. to the right in the fourth intercostal space. The rhythm of the heart was totally irregular. Auscultation was not entirely satisfactory at the time of admission because of the many extraneous noises in the chest. However, when the chest cleared somewhat a loud systolic murmur could be heard at the apex, and both systolic and diastolic murmurs could be heard at the base over the aortic area and along the left sternal border. The liver was enlarged and slightly tender, the edge was easily felt approximately 10 cm. below the costal margin in the midclavicular line. The spleen was not palpable. Shifting dullness was present in both flanks. There was pitting edema of the chest and abdominal walls as well as massive, pitting edema of the hips, scrotum, penis, thighs, legs, ankles and feet. There was no clubbing of the fingers or toes. There was no lymph-node enlargement.

The temperature was 98.6°F, and the respirations 26. The heart rate at the apex was 100 and at the radial artery was 88 per minute, a pulse deficit of 12 beats per minute. There was no capillary pulse. The blood pressure was 130/80.

Examination of the blood disclosed a red-cell count of 4,200,000, with a hemoglobin of 13.2 gm per 100 cc., and a white-cell count of 7200, with 69 per cent neutrophils, 26 per cent lymphocytes, 2 per cent monocytes and 3 per cent eosinophils. The urine gave a + test for albumin and the specific gravity was 1.026. The sediment showed occasional red and white cells. The test for sugar was negative. Urobilinogen determination on a freshly voided single specimen was over 2 mg per 100 cc. The blood urea nitrogen was 15 mg, the blood glucose 74 mg, the plasma cholesterol 156 mg, and the total protein 5.2 gm per 100 cc, the icteric index was 9.5. The blood Hinton test was negative.

An electrocardiogram taken on the day after admission showed the heart action to be grossly irregular because of auricular fibrillation. Right-axis deviation was present (four tracings in 1939 had shown a normal sinus rhythm).

A routine teleroentgenogram of the chest (Fig 1) taken on admission showed the heart to be considerably enlarged, measuring 19 cm in its transverse diameter—an increase of 50 per cent over the average for the patient's height and weight. The area of the cardiac shadow was 235.0 sq cm. Both lungs showed moderate congestive changes and edema, particularly on the right. The right costophrenic sulcus was obliterated, probably owing to a small amount of fluid or to old adhesive pleurisy. However, the striking feature of the chest film was a well defined, circular shadow on the right side at the level of the eighth posterior interspace in the region of the transverse (horizontal) interlobar space (Fig 1 A and B). It measured approximately 6 cm in its greatest diameter. Further examination of the x-ray film revealed two additional unusual shadows, one of which had a double contour and was located along the right upper lateral portion of the chest wall (Fig 1 A and B), the other was centrally located at the level of the arch of the aorta and was obscured for the most part by the spine. This shadow was

\*From the Department of Medicine, Rhode Island Hospital and the Department of Medical Sciences, Brown University Medical Department.  
†Haffenreffer Fellow in Medical Sciences, Brown University Medical Department, and the Department of Medicine, Rhode Island Hospital.

best visualized in its entirety in the upper anterior portion of the chest in the lateral view (Fig. 1 *A*, *B*, *C* and *D*). It was circular in outline and measured approximately 6 cm. in diameter.

The patient was put to bed and was given supportive treatment. He was completely digitalized within 48 hours. At

remained irregular. He received ammonium chloride for 3 days and on the 4th hospital day he was given 1 cc. of mercupurin intravenously with an unsatisfactory diuresis. On December 8 he was given intravenous infusions of glucose in water because of dehydration of the tongue and mucous membranes. This resulted in an impressive diuresis and an

the end of that time he appeared somewhat improved but there was little or no change in the edema. He was maintained on 0.1 mg. of digitoxin daily. The lungs showed some clearing but he continued to have a distressing cough productive of considerable amounts of frothy sputum. The apical heart rate was 72 per minute and the cardiac rhythm

obviously decreased in peripheral edema. The weight at that time was 58 kilograms (128 pounds), a loss of 10 kilograms (22 pounds) in the first 6 days of the hospital stay. On the 8th hospital day a second roentgenogram of the chest (Fig. 2) showed a definite decrease in the transverse diameter of the heart from 19 cm. to 17.5 cm. and also considerable clear-

ing of the congestive changes in the lungs. The area of the cardiac shadow was 217.0 sq cm. The shadow in the region of the transverse interlobar fissure and the shadow along

the head and neck, were no longer engorged. All evidence of edema had completely disappeared. The lungs revealed only a few rhonchi and some scattered rales. The patient

ing of the congestive changes in the lungs. The area of the cardiac shadow at that time was 210 sq. cm., a reduction of 25 sq. cm., or 10.6 per cent, from that of the original area. The large circular shadow in the region of the interlobar fissure reported in the original film (Fig. 1) showed a marked reduction in size and now appeared as a narrow fusiform band measuring approximately 5 cm. long and 0.7 cm. wide.

failure had disappeared. The weight averaged 54.5 kilograms (120 pounds). The temperature remained normal throughout the hospital stay. The patient was discharged improved 20 days after admission.

Eighteen days after discharge, a follow up roentgenogram of the chest (Fig. 4A and B) showed continued improvement. The original shadow was represented by a narrow line

A lateral chest film taken at the same time revealed the middle lobe of the right lung well outlined by the remnants of the effusion in the interlobar space (Fig 4 C and D)

### DISCUSSION

The patient was admitted as an ordinary case of rheumatic heart disease with a severe degree of congestive heart failure. Apparently, this was his first episode of failure. Routine anteroposterior and lateral roentgenograms of the chest taken on admission revealed the unusual shadows described. On admission there was some question of their origin. Although localized interlobar effusions are most commonly of pneumonic or tuberculous origin<sup>7, 12</sup> the negative history of a pulmonary infection and the absence of fever were against either localized collections of empyema or pulmonary tuberculosis with localized areas of pleurisy with effusion. The absence of chest pain, hemoptysis, and thrombosis of the peripheral venous system was evidence against the diagnosis of multiple infarctions of the lung. The striking clinical improvement that followed ordinary therapeutic measures (bed rest, digitoxin and diuretics) and the simultaneous regression of the shadows immediately ruled out the possibility of primary or metastatic carcinoma and obviously made multiple, localized pleural effusions as a manifestation of heart failure the most probable diagnosis.<sup>13</sup> Of interest was the absence of physical signs over the areas noted in the roentgenograms. Naturally no attempt was made to aspirate these areas.

In the previously reported cases of interlobar effusion associated with heart failure in which post-mortem examinations were done<sup>3, 5, 8</sup> either local adhesions or adhesive pleurisy with obliteration of the entire pleural cavity with the exception of the small space between the lobes of the lungs was found. This resulted in the accumulation of serous fluid within the free space. A study of these cases indicates that the transverse interlobar space is the most common site of interlobar effusions. On the other hand the evidence suggests that effusion in the long or oblique fissure is unusual and that multiple, localized pleural effusions as a manifestation of congestive heart failure are extremely rare.

The location of the loculations of fluid in the case presented was interesting. Repeated roentgenograms of the chest revealed beyond question that the circular shadow in the right middle-lung field was in the transverse interlobar fissure.

It may be assumed that the shadow along the right upper lateral area of the chest wall was due to a loculation of serous fluid in an area in the pleural cavity where no adhesions were present between the visceral and parietal pleura.

The shadow centrally located in the anterior portion of the chest at the level of the arch of the aorta was of particular interest, not only because of its location but also because it was the first of the

shadows to disappear. It was believed that this shadow was due to a loculated serous effusion in the anterior superior paramediastinal space.

Schwedel<sup>13</sup> makes the statement that interlobar effusions are characteristically the first to disappear after an effective diuresis or digitalization, or both. He attributes this rapid disappearance either to the small amount of fluid that is usually present in an interlobar space or to the fact that the fluid is enveloped by two visceral pleural surfaces, each of which might promote more adequate absorption than the parietal pleura. However, the rapid disappearance of the anterosuperior paramediastinal effusion and the loculation of fluid in the right upper lateral portion of the chest wall long before the disappearance of the interlobar effusion indicates that there may be exceptions to the sequence described in his statement.

As in many cases of interlobar effusion studied, no antecedent history of an inflammatory reaction of the pleura or pneumonia could be obtained. Although pleural reactions are common in repeated episodes of congestive heart failure one is hardly justified in using this explanation in the case reported above, since this was the patient's first bout of decompensation.

### SUMMARY

A case illustrating multiple, localized pleural effusions as a manifestation of congestive heart failure is presented.

That these findings are somewhat unusual in heart failure is indicated by the fact that no record of a similar case has been found in the literature.

I am indebted to Dr. Lawrence A. Martineau, director of the Department of Roentgenology, Rhode Island Hospital, for his co-operation in this study.

## THE INEFFECTIVENESS OF ALUMINUM SUBACETATE IN RHEUMATOID ARTHRITIS\*

ALFRED BLAZER, M.D.,† H HAROLD FRIEDMAN, M.D.,‡ AND OTTO STEINBROCKER, M.D.§

NEW YORK CITY

**ENCOURAGING** results from the use of aluminum salts in the treatment of 12 patients with rheumatoid arthritis, active and inactive, were reported by Helfet.<sup>1</sup> In an effort to evaluate this therapy we employed aluminum salts according to his method for the treatment of a comparable series of patients with this disease. This report presents our results.

Helfet predicated the use of aluminum salts in rheumatoid arthritis upon certain theoretical premises, which are briefly summarized as follows: The first of these was that, regardless of the etiology, the symptoms of rheumatoid arthritis are the outcome of a secondary or physiologic hyperparathyroidism, he regarded the clinical features of rheumatoid arthritis as in many ways analogous to those of hyperparathyroidism. The second was the theory that parathormone is primarily concerned with the regulation of phosphorus metabolism exercised by control of the blood inorganic phosphate level.

Helfet proposed and tried the use of aluminum salts in rheumatoid arthritis according to the foregoing postulates from which he deduced the following rationale. Since the major fault in the disease according to his reasoning, lies in an overproduction of parathormone with its attendant decalcification of the bones, removal of the stimulus responsible for hypersecretion of the hormone — the blood inorganic phosphate level — should be the effective point of attack. Reduction of the blood phosphate level may be accomplished by a low phosphorus intake in the diet, but such a diet is impractical. An alternative procedure is the administration of aluminum salts orally. These combine with phosphate in the bowel, and the resulting precipitate of insoluble aluminum phosphate is excreted unchanged. The absorption of phosphate is thereby diminished, and the blood phosphate level held down. Less parathormone is then secreted, he reasoned, and in turn less calcium is drained from the skeleton.

A discussion of the pros and cons of Helfet's speculative concepts of the etiology of rheumatoid arthritis, or of parathyroid function, and the influence of aluminum salts is beyond the scope of this paper. We have been interested in the use of aluminum therapy primarily to evaluate its empirical value in rheumatoid arthritis.

Helfet administered to his patients 4 cc of a 2.5 per cent solution of the aluminum salt (either aluminum acetate or aluminum gluconate) four times daily. All patients, in addition, received at least a pint of milk daily to prevent the possible development of rickets from overdosage of aluminum salts. No toxic reactions were noted. Constipation, when present, was easily controlled with mineral oil.

With this regime alone, and without adjuvant therapy of any sort, marked clinical improvement was reported. Of 15 patients, including 12 cases of rheumatoid arthritis and 3 of ankylosing spondylitis, 12 improved in color, 10 increased in weight, and 9 described great relief from joint pain. Only 2 were unimproved. The response of the patients was manifested within three or four weeks by a sense of well-being, improved complexion, appetite and energy as the outstanding benefits. Increased motion was noted in all articulations except those previously ankylosed. In some cases the spindle-shaped swelling of the finger joints disappeared.

## METHODS

Twelve patients with rheumatoid arthritis in different stages of the disease comprised our series. Study of a group as large as Helfet's was initiated for comparison of results to determine whether further investigation of aluminum therapy in a large series of patients was warranted. Patients in this program did not receive any other treatment. Simple analgesics and local physical therapy were permitted when discomfort was severe.

Patients were classified as presenting the early, moderate advanced or terminal stage according to the severity of the signs.<sup>2</sup> The rheumatoid status was designated as active or inactive. The latter showed definite osteoporosis in addition to other clinical features to serve as objective guides to response to this treatment. Of the 12 cases 4 were early, 4 others moderate, and another 4 were advanced. Prior to the start of therapy 8 of the 12 cases were active, and 4 were inactive.

All patients received 4 cc of a 2 per cent solution of aluminum acetate four times daily in addition to a quart of milk daily. This treatment was sometimes supplemented by periodic placebo injections of isotonic saline solution to avoid any prejudice in the minds of those expecting the customary "injections for arthritis" given to many of the other patients in the clinic.

‡Fellow in medicine, New York University College of Medicine.

§Associate clinical professor of medicine, New York University College of Medicine, and assistant physician, Bellevue Hospital.

Radiographic studies and determinations of the erythrocyte sedimentation rate and blood calcium, phosphorus and phosphatase were performed periodically

All patients were followed for from one to two years. Evaluation of the response to treatment was carried out by means of the criteria provided in our therapeutic score card<sup>3</sup>

### RESULTS

Of the 12 patients observed under aluminum salt therapy, 1 showed great improvement, and another, slight improvement, the status of the others was unchanged. In the objective evaluation of response to treatment in rheumatoid arthritis, only evidence of arrest of the disease or great improvement is significant. Owing to the possibility of spontaneous partial or complete remission in this condition, the great improvement exhibited by 1 of 12 patients is of doubtful importance. One case of slight symptomatic improvement carries even less weight.

Among the 8 active cases there was no demonstrable influence upon the rheumatoid process.

No significant alterations in the blood chemical findings were noted. No toxic reactions occurred.

Recalcification of the bones is a rare phenomenon in active or inactive rheumatoid arthritis<sup>4</sup> within the short periods involved here. It does occur, however, on occasions spontaneously.<sup>5</sup> If it were produced in enough of these patients in such a relatively brief interval, it would indicate therapeutic action confirming some of Helfet's theories for this disease. In all but 1 case the decalcification of the bones was unchanged or had progressed farther. After about fifteen months of aluminum therapy x-ray films in 1 case showed at best a slightly suggestive appearance of recalcification of the bones.

### SUMMARY

Twelve patients with rheumatoid arthritis were treated with aluminum salts for a period of from one to two years.

No appreciable improvement in the subjective and objective signs of activity occurred, nor was the course of the disease significantly influenced in 11 of the 12 patients.

Recalcification of the osteoporotic bones did not appear in the roentgenograms of 8 patients with active rheumatoid arthritis and of 3 inactive cases. In 1 case of inactive rheumatoid arthritis there were suggestive signs of slight recalcification.

Repeated estimations of the blood calcium and phosphorus before and during treatment revealed no significant alterations.

Aluminum subacetate demonstrated no significant therapeutic value in these patients.

## MEDICAL PROGRESS

## THE ROLE OF PLEUROPNEUMONIA-LIKE ORGANISMS IN GENITOURINARY AND JOINT DISEASES\*

LOUIS DIENES, M.D.,† MARIAN W. ROPES, M.D.,‡ WILLIAM E. SMITH, M.D.,§

SARABELLE MADOFF AND WALTER BAUER, M.D.¶

BOSTON

ORGANISMS belonging to the pleuropneumonia group (L organisms<sup>||</sup>) were first cultured from the human genitourinary tract in 1937<sup>2</sup> and have been recovered from this tract by several investigators since that time.<sup>3-5</sup> No disease in human beings has yet been ascribed to such organisms, although they are known to cause important epizootic diseases in animals. This paper presents further observations on the incidence of these micro-organisms in human beings, with a discussion of their pathogenicity.

The first organism of this type was cultivated in 1898 from cattle<sup>1</sup> and recognized as the cause of one of the most important plagues of this species, bovine pleuropneumonia. It attracted considerable attention because its cultural and microscopical characteristics differed from those of the established classes of micro-organisms. It had properties common to the viruses, being filtrable and invisible in highly infectious tissues or body fluids. In contrast to viruses, however, it could be cultivated in lifeless mediums. Its growth rendered liquid mediums slightly turbid, and on solid mediums numerous tiny colonies developed. The individual organisms could not be seen in the cultures themselves or in the stained smears usually employed in bacteriology. It has since become apparent that the organism is so soft and fragile that it is destroyed during the preparation of the smears. The introduction of appropriate technic, however, has revealed that the cultures consist of small granules and of fine filaments, both of which may swell, forming soft, spherical forms of various sizes. The latter reproduce again the granules and filaments. This reproductive process, which is very different from binary fission, is probably the most characteristic property of the organism. Although the organism differs

considerably from bacteria, the differences between the two groups are only apparent, and the organism of bovine pleuropneumonia is in our opinion, for the reasons given in a previous review,<sup>11</sup> essentially a bacterium.

For twenty-four years this organism was the only one of its kind that was known. In 1923 an organism of similar properties was discovered as the cause of the disease known as agalactia in goats and sheep.<sup>12</sup> During the past twelve years similar organisms have been recovered from dogs, rats, mice and human beings, and have been found as saprophytic organisms in sewage and soil.<sup>13</sup> The most surprising finding has been the discovery of organisms with similar properties in cultures of various bacteria.<sup>11,14</sup> The majority of investigators now consider these to be variant growth forms of the bacteria.<sup>11</sup>

Whatever their source all pleuropneumonia strains are closely similar in the appearance of their colonies, in morphology, in staining and in physical properties. The bovine, goat and rat strains are pathogenic and produce well known diseases. The mouse strains, usually harmless saprophytes, are pathogenic if introduced artificially into mice. All pathogenic strains produce diseases that tend to be chronic. Although the primary localization of the process varies, joint involvement is common in all species of animals. Usually there is a migratory polyarthritis that subsides entirely within a few weeks, but occasionally the joint involvement is more severe, with suppuration and subsequent destruction of articulating surfaces and ankylosis. In mice, intravenous injection of one type of pleuropneumonia organisms (Type B) has been found to produce a chronic, proliferative process leading in many cases to ankylosis of the involved joints in two to five months.<sup>15</sup>

The pleuropneumonia-like organisms can be recognized only by culture. Identification cannot be made in microscopical preparations from lesions since the organisms are usually not visible in stained preparations and are not sufficiently characteristic in dark-field examination. Since the human strains are not pathogenic for laboratory animals, they cannot be recognized by animal inoculations. Cultures, however, are characteristic. Many human strains grow well on mediums used for cultivation of

||Klebschneider used the letter "L" to designate the strains of the pleuropneumonia group that he isolated.

gonococci, provided the mediums contain animal or human serum. We have obtained the best results with sedimented boiled blood agar to which 30 per cent ascitic fluid or 20 per cent human serum has

be recognized only in microscopical preparations. Stained agar preparations are the most appropriate for this purpose. A square of agar from a suspicious area on the plate is placed on a slide. It is covered with a coverslip on which an alcoholic solution of methylene blue and azure has been dried. The space surrounding the agar square between the coverslip and slide is filled with molten paraffin. It is necessary in making these preparations to avoid large bacterial colonies because they often decolorize the stain. The appearance of L colonies

FIGURE 1

A shows a wet, stained-agar preparation of a two-day-old culture from the uterine cervix in which the colonies of the pleuropneumonia-like organisms are deeply stained — the flat, slightly stained colonies are diphtheroids ( $\times 600$ ). B shows a wet, stained-agar preparation of a fully developed colony of pleuropneumonia-like organisms, demonstrating the transformation of the organisms into large round bodies, taken from a pure culture ( $\times 600$ ). C shows sixteen-hour colonies grown from the urinary sediment of a male patient, the tiny colonies being in clusters on and beneath the epithelial cells and a few separate colonies appearing on the agar surface, this photomicrograph was made from a dry-impression preparation, thus making the epithelial cells visible ( $\times 125$ ). D shows the same culture after seventy-two hours' incubation, the periphery of the colonies consisting of small bacillary forms like those illustrated in F and G below ( $\times 125$ ). E shows a wet, stained-agar preparation of young colonies of pleuropneumonia-like organisms in pure culture — the individual organisms are not clearly visible because all colonies were not in the same plane ( $\times 1250$ ). F shows an impression preparation of young colonies on agar after fixation of the agar with Bouin's solution in which the organisms appear as small polar-stained bacilli, Giemsa stain was used ( $\times 2000$ ). G shows a Giemsa-stained preparation from a broth culture in which small polar-stained bacillary forms, ring forms and markedly swollen forms are visible ( $\times 2000$ ).

been added.<sup>15</sup> Anaerobic conditions are necessary for many strains. The colonies are well developed in two or three days. Sometimes they are macroscopically visible as pin-point colonies, but often they are only 10 to 20 microns in diameter and can

FIGURE 2 Colonies of Pleuropneumonia-like Organisms in Cultures Made Directly from Specimens, as They Appear in Wet, Stained-Agar Preparations with Low (A and C) and with High (B and D) Magnification

A shows tiny colonies and a small streptococcus colony from a male urethra ( $\times 200$ ). B shows part of the former under high magnification, demonstrating the edge of the streptococcus colony and a few pleuropneumonia-like colonies after two days of incubation — the colonies in this case did not develop to a larger size ( $\times 2000$ ). C shows medium-sized colonies from a prostatic secretion after one day of incubation ( $\times 200$ ). D shows small and medium-sized pleuropneumonia-like colonies from a urinary sediment after sixteen hours' incubation — the contours of two epithelial cells are noticeable in the photograph ( $\times 2000$ ).

in such preparations is so characteristic that they cannot be mistaken for anything else by an experienced observer (Fig 1 and 2). Under suitable conditions, even the tiniest colonies can be recognized. Whether small or large, the colonies not only extend on the surface but also invade the medium. The young colonies consist of small granules, which stain less deeply and are less refractile than bacteria

The organisms on the surface of large colonies grow to large round bodies (10 microns or more in diameter), and as a result of the autolysis of many of these bodies, a foam-like structure develops at the edge of the colonies (Fig 1 B). Because of the softness of the organisms, some of them are always distorted and pulled out to filaments in preparations. The softness of the organism, the formation of large bodies and the extension of the colonies into the medium distinguish the pleuropneumonia-like organisms from other bacteria.

The methods of anaerobic culture and stained agar preparations used in the present study have made possible the detection of pleuropneumonia-like organisms in many cases of genitourinary-tract infection in males in which the organisms would otherwise not have been recognized. These methods have been important also in differentiating pleuropneumonia-like organisms from pleomorphic forms of other bacteria. The procedures differ in many respects from those used by other workers. Microscopical examination of unstained colonies and dark-field examination of broth cultures are unsatisfactory and often misleading. The impression preparations used by Klieneberger<sup>1</sup> and Salaman<sup>2</sup> may lead to errors in the recognition and identification of pleuropneumonia-like organisms since the small colonies cannot be seen and the large colonies are identified merely by the surface layer, the only part that adheres to the glass. This surface layer cannot be distinguished in such preparations from that of colonies of pleomorphic bacteria in which individual organisms swell into large spherical forms.

The tendency toward the production of pleomorphic forms of common bacteria, which are difficult to differentiate from pleuropneumonia-like organisms, is greatly increased by addition of penicillin to the medium to suppress bacterial growth. In our laboratory large spherical bodies have been produced from gram-negative bacilli and from gonococci and other Neisseriae on penicillin-containing medium. With certain bacteria, such as *Haemophilus influenzae* and *Escherichia coli*, the presence of penicillin causes the appearance of organisms that have all the characteristics of the pleuropneumonia group. In this paper, cases from which pleuropneumonia-like organisms were cultured only when antibiotics were given to the patient or were added to the culture medium are not included in the series and are considered only in the discussion.

The pleuropneumonia-like organisms that are cultivated from human beings and that have no apparent relation to other bacteria are characterized at present only by their morphologic and physical properties. It is probable that they do not belong to a single species but represent many strains, which, like the mouse strains, are different in pathogenic action and serologic properties. However, the properties useful in differentiating strains of morphologically similar bacteria, such as growth require-

ments, metabolism and pathogenicity, are not known in these organisms. The cultural differences that we have observed which may or may not represent differences between species, are variation in appearance and size of colonies and difference in adaptation to artificial mediums. Organisms obtained from the female genital tract can usually be cultivated without difficulty. The colonies reach a relatively large size (0.1 to 0.5 mm) and grow easily in transplants. Culture from males is more difficult. In several male patients with severe inflammation of the genitourinary tract, the organism grew only anaerobically. The colonies remained very small (0.01 to 0.05 mm) and in transplants the organisms either did not grow or died out in two or three subcultures. Nelson<sup>11</sup> experienced difficulty in cultivating an organism with similar properties that he isolated from a coryza of chickens. It grew at first in tissue culture alone and started to grow in lifeless mediums only after one hundred and twenty passages. The culture method that we have used is presumably not appropriate for all strains, and with this technic we probably do not succeed in growing the organism from all specimens in which it is present.

Little is known about the serologic properties and pathogenic activity of the human strains, although some serologic differences between strains have been demonstrated.<sup>17</sup> Warren and Sabin<sup>18</sup> studied a human strain isolated by us. They concurred in its classification in the pleuropneumonia group and found it to be serologically different from strains isolated from animals. The human strains have not been pathogenic for mice, rats or guinea pigs except in one litter of young mice that died two to six days after infection.<sup>2</sup> Using antigen prepared from two strains of pleuropneumonia-like organisms isolated from patients with nonspecific urethritis, Beveridge, Campbell and Lind<sup>9</sup> obtained positive complement-fixation tests in 33 and 92 per cent of serums in two series of cases of nonspecific urethritis. However, positive results were obtained also in 7 and 70 per cent of two control series. The serologic studies reported by Wallerstein, Vallee and Turner<sup>19</sup> are difficult to interpret, since the organism used, though resembling the pleuropneumonia-like organisms in a few respects, could not be differentiated from the *Grahamella*. Abundant growth that can be washed from agar mediums such as that reported has not been observed by any investigators with organisms of the pleuropneumonia group.

In human beings the pleuropneumonia-like organisms were discovered first in the female and later in the male genitourinary tract. Material from various other sources, including secretions from the respiratory tract and conjunctiva, pleural, synovial, and spinal fluids and stools, has been examined with similar methods, but, in the absence of penicillin, all cultures have been negative for these organisms with the exception of synovial fluids from 2 pa-

Reiter's syndrome discussed below \* The material cultured included 30 throat swabbings from patients with upper respiratory infections and 15 from cases of active rheumatic fever with or without pharyngitis, 24 tonsils excised for chronic tonsillitis, secretions from 4 healthy conjunctivas and 9 cases of conjunctivitis, joint fluids from 15 cases of rheumatoid arthritis, and 15 stool specimens Beveridge, Campbell and Lind<sup>9</sup> found no pleuropneumonia-like organisms in 4 patients with atypical pneumonia, in 57 washings from infected antra or in 70 excised tonsils Perhaps the discovery of more appropriate

TABLE 1 *Clinical Findings in the 58 Women Yielding L Organisms in Cultures from the Cervix or Vagina*

CONDITION OF PATIENT	NO OF CASES

media and more extensive use of anaerobic cultivation will demonstrate the presence of the L organism in some of these locations

Cultivation of pleuropneumonia-like organisms in human beings from sites other than the genitourinary tract has been reported only by Herschberger, Dantes and Schwartzman<sup>20</sup> In blood cultures from a patient with subacute bacterial endocarditis they found an organism that they were unable to identify From their description it seems probable, as mentioned above, that the organism did not belong to the pleuropneumonia group but, as the authors suggest, to the *Grahamella*

After the discovery of L organisms in an abscess of a Bartholin's gland in 1937,<sup>2</sup> a study was undertaken to determine the incidence of these organisms in the human genitourinary tract † All routine genitourinary specimens sent to the bacteriologic laboratory over a period of three months were examined for L organisms The specimens were, in most cases, submitted for examination for gonococci and were planted immediately by the physician taking the specimen on 30 per cent ascitic-fluid-infusion agar plates containing 1 per cent neopeptone

\*Pleuropneumonia-like organisms have been found in cultures from the respiratory tract when penicillin has been given to the patient or added to the cultures to suppress bacterial growth As pointed out above, these organisms represent a variant growth form of other bacteria, often *H. influenzae* In a series of 17 throat and sputum cultures in which penicillin was added to the medium pleuropneumonia-like organisms were isolated in 12 whereas the same specimens cultured on penicillin-free media were negative for L organisms Similar organisms, together with *H. influenzae*, were cultured from the sputum of a patient with lung abscess intensively treated with penicillin aerosol and from a suppurative lesion of the jaw treated with penicillin In all these cases the pleuropneumonia-like organisms were variants of other bacteria produced under the influence of penicillin Nothing is known of their pathogenicity

†We are indebted to Drs J V Meigs and Langdon Parsons of the Massachusetts General Hospital for their aid in carrying out this study

and 2 per cent boiled horse blood This series included 214 specimens from the uterine cervix and 8 from the vagina, urethral discharges from 4 female patients, purulent material from 18 patients with suppurative processes connected with the female genital tract (Table 2), 60 prostatic secretions and purulent discharges from 11 male patients with urethritis The L organism was present in 26 per cent of the cervical cultures of the above series (Table 2) It was also found in the suppurative processes originating from the female genital tract but in a lower proportion of cases

The incidence in the female genitourinary tract in this series was in the same range as that reported by other investigators Klieneberger-Nobel<sup>15</sup> found L organisms in only 14 per cent of 50 pregnant women but noted a much higher incidence (33 to 40 per cent) in the vagina in women with pathologic conditions of the genitourinary tract Similarly, Salaman<sup>8</sup> reported much higher percentages of positive cultures (44 to 75 per cent) in women with various inflammatory conditions of the genitourinary tract than in normal women (6 per cent) Beveridge, Campbell and Lind<sup>9</sup> obtained positive cultures in 17 per cent of 101 "apparently normal women" attending the gynecologic clinic

Clinical data on the 58 women of the original series with positive L cultures are presented in Table 1 The organism was present in 6 cases without any evidence or history of genitourinary disease It was associated with the gonococcus in 11 cases and remained in the cervix after the gonococci disappeared The relatively high incidence of

TABLE 2 *Recovery of Pleuropneumonia-Like (L) Organisms from an Unselected Series of Specimens from the Human Genitourinary Tract*

SOURCE	TOTAL NO OF PATIENTS	PATIENTS WITH L ORGANISMS	PER CENTAGE
Cervical secretion	214	56	26
Vaginal secretion	8	2	25
Urethral discharge (female patients)	4	0	0
Bartholin abscess	6	1	17
Salpingitis	8	1	13
Peritonitis arising from salpingitis	4	1	25
Prostatic secretion	60	5	8
Urethral discharge (male patients)	11	1	9

this organism in the female genital tract suggests that it is part of the bacterial flora in this location However, its presence in suppurative processes suggests that it occasionally has some pathogenic action in the female genital tract Since the original series of unselected cases was completed, we have searched for L organisms in various types of inflammation of the female genitourinary tract and have obtained further suggestion of its pathogenicity We have cultivated the organism from Bartholin's abscesses in 6 cases and from a pelvic abscess associated with puerperal infection and from one associated with salpingitis The organism was associated

with other bacteria except in 2 cases of Bartholin's abscess (Case 1)\*. In 6 cases of acute and chronic vaginitis and cervicitis the *L* organism was present in pure culture (as in Case 2) and in 17 other cases was found in much greater abundance than other bacteria. In some of these cases the acute inflammatory condition developed a few days after sexual exposure. Such observations lend support to the hypothesis that the organism is pathogenic under certain conditions and indicate the necessity for further studies of its role in inflammatory conditions of the female genitourinary tract.

In male patients the incidence of *L* organisms in the genitourinary tract is much lower than that in females. In the original series of routine cultures discussed above, the incidence in males was 8 per cent (Table 2). Beveridge<sup>6</sup> isolated pleuropneumonia-like organisms in 4 of 24 cases of nongonococcal urethritis in males. Salaman<sup>8</sup> found *L* organisms in 4 out of 28 men without any evidence of urethritis and in 3 of 45 cases of nonspecific urethritis. Johnston<sup>7</sup> isolated *L* organisms in 2 cases of nonspecific urethritis. Beveridge, Campbell and Lind<sup>9</sup> cultured pleuropneumonia-like organisms from 14 of 70 urethral washings from patients with nonspecific urethritis, from 67 normal male medical students they obtained no positive cultures. The incidence in these series might have been higher if stained agar preparations had been used since small *L* colonies may not have been recognized by the methods employed.

This difference in incidence of *L* organisms in the male and female genitourinary tracts has also been apparent in the many cultures taken during and after gonococcal infections, examined since the original series of unselected specimens was completed. These specimens have also afforded opportunity to determine the frequency of association of gonococci and *L* organisms in the genitourinary tract. In cultures from female patients the two organisms were often found together. In our original series the *L* organism was found in association with the gonococcus in 11 female patients, and in the 5 cases followed, the *L* organisms remained in the cervix after the gonococci had disappeared. In male patients, on the other hand, none of the 6 cultures that showed gonococci were positive for the *L* organism. In fact, *L* organisms have been found, in our laboratory, in only 2 cultures from the male urethra or prostate that were positive for gonococci and in only 1 case in cultures obtained immediately after the cure of a gonococcal infection. It is apparent that pleuropneumonia-like organisms are not common inhabitants of the male genitourinary tract as they are in female patients. Salaman<sup>8</sup> reported positive cultures for *L* organisms in 12 of 35 cases of gonorrhea in men. However, as mentioned above, the addition of penicillin to the

culture medium causes production of large spherical forms of gonococci and other bacteria, and differentiation of such pleomorphic forms from pleuropneumonia-like organisms is extremely difficult in the impression preparations used by him.

A study of the male patients from whom positive cultures for pleuropneumonia-like organisms were obtained gave more definite evidence of the pathogenicity of these organisms than that in the female patients. The organisms have been found in 58 male patients, including the 6 cases in the original routine series (Table 2). All had evidence of prostatitis or other genitourinary-tract infection at the time of the isolation of the organism. In 1 patient (Case 12) *L* organisms were first cultured from the prostate during an acute attack of urethritis, arthritis and intis. Eighteen months later cultures of the prostatic secretion were negative for *L* organisms. However, during an attack of urethritis, arthritis and conjunctivitis, apparently precipitated by prostatic massage, an abundant growth of *L* organisms in pure culture was obtained from the prostate. In 12 cases the *L* organisms were grown in pure culture. Six of these patients had cystitis (as in Case 11). Another had a penurethral abscess. In the 4 cases of cystitis followed *L* organisms disappeared or decreased markedly in number after the urinary symptoms subsided. These data offer strong evidence that the pleuropneumonia-like organisms were the cause of the urinary-tract infection.

In a control series of 31 patients with chronic, nongonococcal prostatitis, only 1 of the prostatic cultures contained *L* organisms. The technique of culture and examination was the same as that used in the cases of acute or subacute prostatitis in which prostatic cultures were positive for *L* organisms.

Clinical data on the male patients can be presented best if the cases are divided into groups. These presumably indicate the various clinical pictures produced by infection with pleuropneumonia-like organisms. The groups are discussed separately so far as possible, and cases characteristic of each type are presented. Ninety per cent of the patients were between the ages of twenty and forty. In all groups the severity of involvement varied greatly.

In 26 cases the infection was limited to the urethra and prostate without cystitis, arthritis or conjunctivitis. The evidence of urethritis varied, approximately a third of the cases had only a slight discharge (or slight burning on urination) lasting a few days or months (as in Case 3), whereas the remainder had a moderate or profuse purulent discharge persisting for months or even years (as in Case 4). One patient had a penurethral abscess of two days' duration. Similarly, the prostatitis was manifested in a third of the cases merely by slight change in the size and texture of the prostate and a few white cells in the secretion, but in others the gland became large, boggy and tender and massage produced purulent secretion. In 5 cases pure cultures of

\* In 1 case anaerobic cultures were not made so that the possibility that other anaerobic bacteria were present could not be ruled out.

L organisms were obtained from the urethral secretions. In most of this group there was no evidence of systemic involvement, but 2 patients had an erythematous maculopapular rash.

In 9 cases the infection involved the bladder. Symptoms in these patients varied from slight dysuria and frequency in 2 cases to severe pain or gross hematuria in the remaining 7. Severe hemorrhagic cystitis was demonstrated by cystoscopy in 4 cases. The urine yielded abundant growth of pleuropneumonia-like organisms in pure culture in 6 cases and was associated with a few colonies of diphtheroids, staphylococci, *Esch coli* or streptococci in the others. In a higher percentage of these patients with cystitis (8 of 9 cases) than in those with

or iritis who presented the typical picture of Reiter's syndrome.

In the patients with chronic joint involvement, the evidence of urinary-tract infection antedated the onset of the arthritis in all but 1 patient, a sixty-nine-year-old man with typical rheumatoid arthritis of thirty-three years' duration. The joint symptoms in this group consisted usually of stiffness, aching and slight swelling that persisted for months or years (as in Case 6). It is impossible to determine whether there was any relation between the joint involvement and the urinary-tract infection in these cases.

The joint involvement in the acute cases was usually sudden in onset, polyarticular and often

\*In all patients pleuropneumonia like organisms were cultured from the genitourinary tract and in patient R F and Case 440884 from the synovial fluid.

†The cases without numbers were from outside hospitals. The last 7 cases presented the characteristic picture of Reiter's syndrome.

uncomplicated urethritis and prostatitis, the infection persisted for many weeks. In 3 cases it recurred frequently over the course of several years. It is in this group that the effect of streptomycin therapy was most impressive, as pointed out below. Evidence of systemic involvement was present in only 2 of these patients. They had the characteristic picture of Reiter's syndrome and are discussed in that group.

The presence of constitutional symptoms (fever, chills and malaise) and joint involvement in many of the male patients with positive cultures for pleuropneumonia-like organisms suggests that these organisms produce a generalized infection with joint localization. Arthritis was present in 27 cases, but the type varied considerably. They can be divided into cases with subacute or chronic joint involvement (9 cases) and those resembling infectious arthritis in the acuteness of onset, the tendency to migration and the degree of pain, tenderness and heat of the involved joints (18 cases). The acute group can be further subdivided into 9 cases without eye involvement and 9 patients with conjunctivitis

migratory (Cases 7, 8 and 9). In 6 cases it was associated with fever and malaise and in 2 cases with chills. Two patients had skin rashes, maculopapular in 1 and vesicular in the other, and another had a balanitis. The affected joints were usually swollen, very painful and tender and occasionally somewhat reddened. The effusions usually persisted for long periods, often for months. The cytologic and chemical findings in the synovial fluids obtained in 6 cases are summarized in Table 3. The total leukocyte and polymorphonuclear counts were lower and the sugar contents higher than those found in comparable cases of infectious arthritis due to pyogenic organisms.<sup>21</sup> Similarly, the mucin precipitated with acetic acid formed a tighter clump in most of these fluids than in effusions from other types of infectious arthritis. Despite the evidence of rather severe inflammation given by the synovial-fluid findings (Table 3), the only roentgenographic change observed to date is moderate decalcification of the bones around the involved joints.

The clinical picture in 9 cases was characteristic of Reiter's syndrome, consisting of urethritis, arthri-

tis and conjunctivitis (Cases 11 and 12). The genito-urinary and joint involvement resembled that of the other cases with acute arthritis. The synovial-fluid findings in 7 cases are given in Table 3. The conjunctivitis was usually moderately severe, often with purulent discharge and persisting for one or two weeks. In 2 cases there was only slight redness, burning and discharge lasting one or two days. Iritis was present in 2 of the cases, but no patients had corneal ulcers. Balanitis, consisting of superficial papulovesicular or ulcerated lesions, was noted in 5 patients. Stomatitis was present in 2 of these. Three patients had generalized skin lesions, maculopapular and vesicular. Aspiration of vesicles on the plantar surface of the foot in 2 of these cases yielded amorphous material, cultures of which were sterile. Like the patients with uncomplicated urethritis and prostatitis due to the pleuropneumonia-like organisms, the patients with Reiter's syndrome showed a tendency toward recurrence of the disease, 5 out of 9 having recurrences. One patient (Case 12) has been seen in 5 attacks during the past six years.

(To be concluded)

## MASSACHUSETTS MEDICAL SOCIETY

## PROCEEDINGS OF THE COUNCIL

Stated Meeting, February 4, 1948

A STATED meeting of the Council was called to order by the president, Dr Edward P Bagg, Hampden, on Wednesday, February 4, 1948, at 10 30 a m in John Ware Hall, 8 Fenway, Boston One hundred and ninety-seven councilors (Appendix No 1) were present

After opening the meeting and introducing the new secretary, Dr H Quimby Gallupe, Middlesex South, the President read the following obituary

WILLIAM J PELLETIER — "No physician, insofar as he is a physician, considers his own good in what he prescribes, but the good of the patient" according to the pronouncement of Plato in the third century B C The truth of this axiom, particularly regarding the physician's own health, has been demonstrated once more to our profound sorrow in the twentieth century, A D, through the death in the prime of life of our fellow councilor, William J Pelletier, who had just turned fifty years

One of Tufts' most brilliant graduates, he furnished an outstanding example of what a talented physician can mean in the life of a smaller community, not only by the skillful laying on of hands but also by the breadth of his interests and the strength of his upright, friendly character Throughout the upper Pioneer Valley, he was favorably known as a practitioner of medicine As a surgeon, he won membership in the American College of Surgeons For years he handled acceptably the medicolegal problems of the Eastern District of Franklin County as associate and since 1943 as chief medical examiner

Dr Pelletier volunteered for military service in the United States Army in World War I During World War II he acted as physician to his Selective Service board when disabilities kept him out of uniform

A past president of the Franklin District Medical Society and long-time member of the Council, he was always alert and ready, so long as his strength permitted, for whatever work was assigned to him in the Massachusetts Medical Society His counsel will be missed in the affairs that concern us all, but even more so in his hometown, Turners Falls, where he served so splendidly as a citizen in various capacities, including those of school physician and member of the Board of Health Most acutely, outside the family circle, the Farren Memorial Hospital will suffer through the loss of Dr Pelletier, a former president, who did so much to improve the facilities of the institution in anticipation of the growing clinical needs of his fellow citizens

Like Dorcas of Joppa, this man was "full of good works and alms-deeds which he did" A modern Luke, he was a beloved physician worthy of the name who did not "live unto himself" alone

May peace be his reward, well deserved and without end

The President then said that he had just been notified of the passing of Dr Isaac S F Dodd, of Pittsfield, vice-president of the society in 1947, and that since it was impossible on such short notice to do justice to his work and character, he was postponing his memorial until the next Council meeting

At the request of the President, the Council stood for one minute in silent tribute to the two departed members of the Council

The Secretary presented the record of the October, 1947, meeting of the Council as published in the

*New England Journal of Medicine*, issue of December 4, 1947, and moved its acceptance The motion was seconded by Dr Eliot Hubbard, Middlesex South, and it was so ordered by vote of the Council

## APPOINTMENTS

The President then announced the following interim appointments

To the Committee on Postgraduate Medical Education Dr John F Conlin, Suffolk, to replace Dr Robert N Nye, deceased

To Represent the Massachusetts Medical Society on the Board of Trustees of the Boston Medical Library, retroactive to January 1, 1948

Dr Curtis C Tripp, New Bedford, to serve for 1948

Dr John J Curley, Leominster, to serve for 1948-1949

Dr Edward S O'Keefe, Lynn, to serve for 1948-1949-1950

Dr Albert Ehrenfried, Boston, to serve for 1948-1949-1950-1951

Delegates to Annual Meetings of New England State Medical Societies

Connecticut, Dr Raymond L Barrett, Springfield  
Alternate, Dr John Pallo, Westfield

New Hampshire, Dr William M Collins, Lowell  
Alternate, Dr Ralph E Cole, Westford

Maine, Dr Harold G Giddings, Boston  
Alternate, Dr Lincoln C Peirce, Newburyport

Rhode Island, Dr Harold E Perry, New Bedford  
Alternate, Dr William Mason, Fall River

Vermont, Dr Warren D Thomas, Montague  
Alternate, Dr John B Temple, Shelburne Falls

The President asked for confirmation of these appointments, and it was so ordered by vote of the Council

## REPORTS OF COMMITTEES

Committee on Public Relations — Dr Harold R Kurth, Essex North, Secretary

President Bagg stated that according to the circular of advance information (Appendix No 2) the first item was to consider whether or not to approve the objectives of the National Physicians Committee, and that Dr Channing Frothingham had been given a hearing before the Committee on Public Relations, since time was not sufficient at the last meeting of the Council Also, a letter from Dr Frothingham had been published in the *New England Journal of Medicine*, issue of November 20, 1947

The National Physicians Committee had sent Mr M H Peterson to attend the last meeting of the Executive Committee The President asked the Secretary to read a résumé of Mr Peterson's remarks (Appendix No 3)

The Secretary then moved the approval of the objectives of the National Physicians Committee. This motion was seconded.

Dr Channing Frothingham opened the discussion as follows:

I should like to say that as I go around the country not only among the laymen but also among the medical profession there are a good many people who doubt the sincerity of the National Physicians Committee and also admitting that the National Physicians Committee is sincere, there are a good many who do not approve of its methods.

Later this morning you will be asked to raise your contribution for information regarding medical legislative service which is produced by Marjorie Shearon and I should like to give a short quotation from Marjorie Shearon concerning the National Physicians Committee:

The National Physicians Committee is still another inimical force working against the medical profession from within. This organization I regard as second only to the medical politicians in their threat to American medicine.

A letter from Marjorie Shearon which she sent around to members of the medical profession and others interested contains the following statements:

I have refused to co-operate with the National Physicians Committee because the publications of that committee have been misleading and have failed to give to the medical profession the carefully prepared scientifically accurate and objectively informative material which the profession should have.

The facts about nationalization of medicine speak for themselves and are embellished are sufficiently alarming.

Evidence given at the hearing on S 1606 indicates the National Physicians Committee receives a considerable proportion of its backing from the drug industry. Why should the medical profession which is a reputable and honorable one altruistically devoted to the service of humanity have its educational campaign or more correctly speaking its legislative lobbying activities financed in considerable measure by a purely commercial group such as the drug industry?

The National Physicians Committee from its own testimony appears to be vulnerable in its dealings with the Bureau of Internal Revenue.

Mr Edward F Stegen associate administrator of the National Physicians Committee has not in my opinion, conducted himself in accordance with accepted professional standards of conduct.

The Washington representative of the National Physicians Committee, Arthur L. Conrad, associate administrator of the National Physicians Committee, in my opinion is exceptionally unqualified to represent the physicians and surgeons of the United States.

I am not convinced the National Physicians Committee discussion groups which early in May delivered a statement of high policy regarding national health legislation really represented the medical profession or was working in the best interests of the profession.

I doubt if the members of the Board of Trustees of the National Physicians Committee who are I take it physicians of high standing and unquestioned probity have any clear picture of what goes on in Washington in their name.

For these reasons I urge the Council to explore the sincerity and activity of the National Physicians Committee before giving it its stamp of approval.

President Bagg asked for any further discussion. Dr Reginald Fitz, Suffolk, drew attention to the fact that the committee to meet with the Committee on Medical Economics had not reported and that Dr Gallupe's motion was out of order, and Dr Fitz moved that the motion to approve be tabled.

until the report of the committee was received. Dr Carl Bearse, Norfolk, seconded this motion. It was so voted.

Dr Bagg stated that the matter could be referred back to the Committee on Medical Economics.

Dr Bagg then stated that the matters concerning Blue Shield, referred to Dr McCann's subcommittee, would be resubmitted to the Committee on Public Relations at the next meeting.

Dr Bagg then called attention to a resolution in the report of the Executive Committee report (Appendix No 4) in which Dr Curley moved to approve the changes in the by-laws suggested in a letter from Dr Bagoall, to the effect that the president of Massachusetts Medical Service, Inc, and the medical director thereof be made members of the Council. This motion was seconded by Dr Wheeler and unanimously approved by the Executive Committee.

Dr Bagg asked the pleasure of the Council. Dr Curley then repeated his motion, which Dr Wheeler seconded. Dr Bagnall offered the following amendment to the motion: "If the president of Massachusetts Medical Service be a physician, and a member of the Massachusetts Medical Society" because the president might not be a physician, and therefore would not be eligible for membership in the Council. Dr Curley accepted the amendment. Dr Bagg called for a vote. The motion was carried.

Dr Bagg then called attention to a statement of Dr Appel's as follows: "The medical staff of the Salem Hospital unanimously opposed the inclusion of professional services in the Blue Cross policy."

Dr Bagg then spoke as follows:

This item was referred to Dr McCann's committee. It seems to me pertinent to speak at this time of the present status of the report of the Special Services Committee which had to do with that topic, and I should like to read you a letter that I wrote to Dr Parkhurst, chairman of the Committee to Meet with the Massachusetts Hospital Association. This is under date of January 30.

Two hundred copies of the reprints of the report of the Committee on Special Services have been sent to the president of the Massachusetts Hospital Association for distribution to member hospitals. After consulting with members of the Committee on Public Relations it seems proper to refer these stated principles of the physician hospital relations to your committee to meet with the Massachusetts Hospital Association.

I should like to add the name of Leland S. McKuttrick to your Committee inasmuch as he was chairman of the Special Services Committee, and is vitally interested in the matter.

The ultimate application of these principles of course must rest with the members of the Society who compose the medical staffs of individual hospitals. Approval of the Council for this action will be sought at the next stated meeting.

That is today. I have a letter under date of January 28 from the secretary of the Massachusetts Hospital Association, as follows:

We are today in receipt of 200 reprints of the Report of the Committee on Special Services. They are being mailed out today to member hospitals.

As you recall that report was approved at the October meeting of the Council and it was published in the *Journal* in December. The difficulty that has held it up so long

was to get reprints. They were finally made available, after the middle of January, and they have gone out.

I have a letter from Dr McKittrick stating that he would be very glad to serve, if the Council so wishes. What I should like to know now is whether the Council approves of this disposition of the matter.

Dr Hornor moved approval of the President's action. The motion was seconded by Dr Bagnall and unanimously voted by the Council.

Dr Bagg then asked Dr John F Conlin to report on the Women's Auxiliary and other matters.

Dr Conlin then stated that three auxiliaries had been organized and six others were in the process of organization. He asked the co-operation of the officers of the district medical societies toward the formation of auxiliaries so that a state auxiliary could be formed.

Dr Bagg then asked for approval of the recommendations to expend \$50 to help the State Nurses' Association publish a fact sheet on schools of nursing in Massachusetts.

Dr O'Hara moved that the recommendation be approved. Dr Bagnall seconded the motion, which was carried.

Dr Bagg asked the pleasure of the Council regarding the approval given by the Executive Committee to the action of the Public Relations Committee in increasing the fee of the Marjorie Shearon Service from \$200 to \$500.

Dr Dunlop moved to increase the fee for the Service from \$200 to \$500.

The motion was seconded. It was then discussed by Drs Channing Frothingham, Dwight O'Hara, Elmer Bagnall, Augustus Thorndike and Reginald Fitz.

Dr Buck explained that the Committee on Finance had approved the expenditure by the Committee on Public Relations as reasonable. Dr Bagnall stated that the matter was one of approval or not of the President's action in emergency appropriations. Dr Leroy E Parkins, Suffolk, questioned the importance of the Shearon Service.

Dr Allan M Butler, Suffolk, stated that the committee had a right to buy information needed but questioned the advisability of the Society's subscribing to a particular service.

Dr Bagg stated the question. The motion was passed by a majority vote.

Dr Ober moved the approval of the report as a whole. Dr O'Hara seconded this motion, and since there was no discussion, the motion was carried.

#### STANDING COMMITTEES

*Committee on Publications* — Dr Richard M Smith, Suffolk, *Chairman*.

This report, which is as follows, was presented by Dr Smith.

The Committee on Publications wishes to submit an amendment to the by-laws of the Society, in Chapter IV, Section 1, as follows: omitting the word "and" in the last

portion and substituting a comma, and adding after "committees," the phrase, "and the editor of *The New England Journal of Medicine*." The whole Section will then read:

Section 1. The Council shall consist of counselors chosen by the district societies, the president, ex-presidents, president-elect, vice-president, vice-presidents *ex-officio*, secretary, treasurer, and assistant treasurer of the Society, the secretaries of the district societies, the chairmen of all standing committees and the editor of the *New England Journal of Medicine*.

Dr Smith moved acceptance of the report. Dr Parkins seconded the motion.

Dr Bearse, Norfolk, spoke as follows:

Mr President, I feel at the present moment like a man who is a day late to a funeral. In this present report a recommendation has been made that the by-laws be amended — well, the by-laws have been amended so that the editor of the *New England Journal of Medicine* would be a member of the Council, *ex-officio*.

This particular recommendation has been made very correctly, but when it comes to amending the by-laws, according to the by-laws under which we are now operating, there is a definite formula to be followed.

In the report of the Committee on Publications, that formula has been followed.

Earlier this morning the Council voted to accept a motion to the effect that the director of the Blue Shield and the president of the Board of Directors of the Blue Shield and the medical director be made members of the Council, *ex-officio*.

In order to have this done, a similar motion should have been introduced, as has been done by the Committee on Publications. The by-laws state in Chapter 9, amendments, "These by-laws may be amended by a majority vote at any annual meeting of the Society, provided that the proposed amendment or amendments shall have been submitted previously in writing to the Council."

So far as the action taken by the Council pertaining to the motion made to have the president of the Board of Directors and the medical director members *ex-officio*, that has not been done. Therefore, if this particular recommendation is accepted, so far as the editor of the *Journal* is concerned, it will be for that purpose only, and I should say that the other motion that was passed is out of order.

Dr Bagg replied as follows:

I will state for the information of Dr Bearse and the Council that merely approving of these changes in the by-laws does not make them official. The by-laws state that amendments must be approved by the Council and then submitted with the call to every member of the Society at the annual meeting. It is only at the annual meeting of the Society that by-laws can be changed. But in order to get them in with the Council approval, in the call of the annual meeting, it is necessary to approve them at this meeting. They do not become automatically law. They still have to be ratified by the general body of the members.

Therefore, I would rule that it is not out of order.

Dr Hornor then spoke as follows:

I do not see how we can avoid resubmitting this question to the Council in its May meeting and at the same time having it published in the call for the annual meeting, and as I interpret the by-laws, if the Council at the meeting in May approves of these proposed changes in the by-laws, at the annual meeting they can be approved, accepted or declined.

I therefore think that we should accept the report of the Committee on Publications and also that it would be in order after that report is accepted to submit the changes in by-laws, as we want to have them at the next meeting of the Council, appear in writing to the Council.

All amendments must be submitted in writing, as this one has. And if we can accept Dr Smith's report, I should like to submit the exact form of the changes and by-laws.

that we want to have made and have those published in the call of the May Council meeting and then go to the annual meeting

Dr. Smith moved that the recommendation be approved and the report accepted. The motion was seconded, and it was so ordered by vote of the Council.

*Committee on Arrangements* — Dr. George G. Bailey, Jr., *Chairman*

This report was presented by the Chairman, Dr. Bailey, as follows:

The Committee on Arrangements reports that plans for the program of the 1948 annual meeting are well under way. It expects to present a well balanced program with interesting speakers who will appeal to the membership of the Society.

Our technical-exhibit spaces have as usual all been sold so that the financial success of the meeting is assured but owing to the fact that we have less space available for sale our profits will undoubtedly be less than they have been in recent years.

Special emphasis is being placed upon the scientific exhibits this year and ten hospitals have been invited to present exhibits. These should be a particularly attractive feature of the meeting.

May 25, 26 and 27 are the dates for the meeting with the Council meeting on Monday evening May 24.

Dr. Bagg stated that he had been able to obtain Mary Ellen Chase, of Smith College, as a speaker for the annual dinner and that unless there was objection he would let the committee report stand as printed.

*Committee on Finance* — Dr. Robert W. Buck, *Chairman*

Dr. Buck moved acceptance of this report (Appendix No. 5) and Dr. Phippen seconded the motion. Dr. Buck then spoke as follows:

The report contains three recommendations. The first one is as follows: The Committee recommends that the appropriation to carry the *New England Journal of Medicine* be increased from \$5000 to \$10,000. As you know the amount that is annually appropriated is usually returned. This recommendation means that we want to appropriate \$10,000 that will not be spent, instead of \$5,000 that will not be spent we hope although if it is necessary that that amount of money should be spent by the *Journal* it will be available as a working fund.

I move the acceptance of the recommendation. The second recommendation is as follows: "The Committee further recommends that the *New England Journal of Medicine* shall return to the Society on December 31 any excess of cash over \$10,000 instead of the present amount of \$6,000 as agreed upon in 1940.

The explanation is again quoted from Dr. Smith. If it is not clear to you perhaps Dr. Smith will explain the implications of this in greater detail.

Dr. Smith then spoke as follows:

Several years ago an arrangement was made with the Finance Committee that at the end of the year the *Journal* should return to the Society whatever funds it had in hand over and above \$6,000. In other words this left us a working capital of \$6,000. At the time that that arrangement was made the budget of the *Journal* was considerably under \$100,000 a year. If you will refer to the report of the Committee this year you will see that that amount is nearly \$250,000 now and a working capital of \$6,000 is rather small.

Last year we returned to the Society \$9,000. This year I am sorry to say we will not be able to return any amount and we had to borrow from the Society \$5,000 which we have returned. If our working capital had been \$10,000 instead of \$6,000 we probably should not have had to borrow money from the Society or if we borrowed at all a very small amount. We are simply asking that the *Journal* be allowed to retain in its fund the sum of \$10,000 at the end of the year instead of the sum of \$6,000 as at present.

Dr. Buck resumed speaking as follows:

The third recommendation of the Committee on Finance is brought about by the discovery that the Society is now liable to taxation. This reads: "The Committee on Finance recommends that the Council authorize the payment of a federal social security and unemployment tax for 1947 amounting to \$507.78 and that provision for such taxation be made in future budgets."

The necessity for this recommendation is apparent from the following communication received by this committee from the treasurer of the Society:

The Internal Revenue Department, Washington, have changed our tax exemption from Code 101 (6) to 101 (7) which still exempts us from federal income tax as a corporation but makes us liable to both social security taxation and unemployment taxation for employees. I consulted with Mr. Dodge, the Society's lawyer, to see if we should take it lying down and he said: "Yes, as the only alternative would be to contest it in court with little prospect of winning."

There seems to be no alternative to accepting this change. I move that this recommendation be adopted.

*Committee on Cancer* — Dr. Shields Warren, Suffolk, *Chairman*

Dr. Warren spoke as follows regarding this report (Appendix No. 6):

You have all had the report in the circular of advance information and therefore I shall not read it to you but simply call your attention to the three recommendations made.

I will remind you that at the October meeting of the Council the report of the Committee on Cancer was not accepted but was by vote of the Council placed on the table.

The first recommendation, therefore, is that the report of the committee presented at the October meeting of the Council be taken from the table. I move that this recommendation be adopted.

Dr. O'Hara seconded the motion, and it was so voted.

Dr. Warren then moved that both reports be accepted by the Council. Dr. Phippen seconded this motion, and it was so voted unanimously.

Dr. Warren moved that the Council approve in principle the establishment of a Cancer Detection Clinic at the Palmer Memorial Hospital.

Dr. Bagnall seconded the motion, and it was so voted.

Dr. Warren moved the acceptance of the report as a whole. Dr. Hornor seconded the motion, and it was so voted unanimously.

*Committee on Postwar Loan Fund* — Dr. George L. Schadt, Hampden, *Chairman*

The report of this committee, which is as follows, was presented by Dr. Eliot Hubbard, in the absence of Dr. Schadt:

The Post War Loan Fund was activated by vote of the Council in October 1945. Thirty-five loans have been

made, four of which were renewals of the original loan. The last loan was made on October 30, 1947. The total amount of the loans was \$17,500.

The Committee is of the opinion that the purpose of the Post War Loan Fund has been accomplished and the need for its existence is no longer evident. The Committee, therefore, recommends that the activities of the Post War Loan Fund be discontinued, and that the Committee be discharged.

Dr Hubbard moved the acceptance of the report.

Dr Ober seconded the motion, and it was so voted.

Dr Hubbard moved the adoption of the recommendation that the committee be discharged. Dr Bagnall seconded the motion, and it was so ordered by vote of the Council.

#### *Advisory Committee on Malpractice Insurance — Dr Carl Bearse, Norfolk, Chairman*

This report was presented by the Chairman, Dr Bearse, as follows:

The Advisory Committee on Malpractice Insurance appointed by the Council to "serve in an advisory capacity to the Society and insurance companies in regard to malpractice suits" has held two meetings. The function and scope of this committee were discussed. It was voted that all members of the Massachusetts Medical Society be urged to carry malpractice insurance (the Society has no funds for payment of verdicts or for expert medical testimony for those members not insured), and that all insurance companies writing malpractice insurance in Massachusetts be notified regarding the existence of this committee and of its desire to co-operate with them. It was also recommended that these companies be asked to furnish this committee with answers to the following questions:

How many suits are actually brought into court each year and what is the disposition of these suits? (Names of physicians involved will not have to be given.) The committee is considering the advisability of having "listeners" at these trials and would like to know how often this might be necessary.

Is it their belief that this committee could be helpful in the selection of experts to testify at suits for malpractice?

Would they desire to have this committee review the testimony of physicians who have testified in a manner that appears to them to be below the standards applicable to members of the Massachusetts Medical Society?

Dr Bearse continued as follows:

This is the first report of a new committee. This committee came into being at the previous Council meeting. Its function is to serve in an advisory capacity to the Society and to insurance companies regarding malpractice suits.

The committee believed that since it is new and its duties are not clearly defined, it should proceed slowly and with caution. No action as yet has been taken. No letters have been sent. We have delayed taking any steps until this report has been acted upon.

The committee believes that all members of the Society should be urged to carry malpractice insurance. The Society has no funds for the payment of damages awarded or for expert medical testimony for members who are not insured.

The committee also believes that the insurance companies writing malpractice insurance in the Commonwealth should be notified regarding the existence of this committee and of its desire to co-operate with them and that these companies should be asked to furnish the committee with answers to the questions asked above. A previous committee, the Committee to Survey the Malpractice Situation in the Commonwealth, tried to obtain the answers to these questions from insurance companies, but without success.

The committee thought it would be helpful to them if they knew how many suits are actually brought into court a year, and what is the disposition of these suits. Names of physicians are not wanted, merely the number and the amounts of money involved.

We should also inform the insurance companies that the committee is considering the advisability of having listeners at these trials and would like to know how often this might be necessary. Incidentally, this was a suggestion made by one of the insurance companies to which we wrote during the course of the survey.

The committee would like to know from the insurance companies whether it could be helpful in the selection of experts to testify at suits for malpractice and also whether the insurance companies would like to have the committee review the testimony of physicians who have testified in a manner that appears to them to be below standards applicable to members of the Massachusetts Medical Society.

Dr Bearse moved the acceptance of the report. Dr Bagnall seconded the motion, and it was so voted.

#### *Report of the Committee of Seven — Dr Reginald Fitz, Suffolk, Chairman*

Dr Fitz pointed out that the report (Appendix No. 7) was divided into two parts, the first recommending that a secretary who devotes his entire time to the work of the Society be henceforth employed. Dr Fitz moved the adoption of that part of the report. Dr Ober seconded the motion, and the Council voted it unanimously.

Dr Fitz stated that the second part of the report dealt with certain suggested amendments to the by-laws and stated that the committee would like to make an amendment by deleting the word "standing" and substituting therefor the word "other."

Dr Fitz stated the committee recommended the acceptance of this part of the report, as so amended.

Dr Bagnall seconded the motion, and it was so ordered by vote of the Council.

Dr Fitz moved the acceptance of the report as a whole. Dr O'Hara seconded the motion, and it was so voted unanimously.

Dr Fitz moved that the committee be discharged. Dr Bagnall seconded the motion, and it was so voted.

#### *Committee on Public Health — Dr Roy J Ward, Worcester, Chairman*

This report, which is as follows, was presented by the chairman, Dr Ward:

The first meeting of this committee was held on September 24, 1947.

The committee approved the inclusion in the State Public Health Nurses' Manual of the use of DDT as one of the recommended methods of treatment of pediculosis capitis. Approval of the committee had been requested by Dr Vlado Getting, commissioner of Health of Massachusetts, prior to publication of a new manual for Public Health Nurses.

The committee also indorsed a proposed change in the present law requiring annual examination of school children. The following motion was adopted: "That this committee approves of a change in the present law and indorses the principle that such examinations be at intervals as may be determined by the Department of Public Health after consultation with the Department of Education."

The problems of increasing pollution of inland and coastal waters were discussed at length by Dr Vlado A. Getting, Dr John E. Gordon and Mr Arthur Weston State Sanitary Engineer. It was noted that the Society has given little attention to this problem for several years and it was voted to request the Committee on Arrangements for the Annual Meeting and the Committee on Postgraduate Education to consider the inclusion of this subject in their programs.

A study is being made of the adequacy of the teaching of public health in medical schools.

It is planned to discuss accident prevention at a future meeting.

Dr Ward stated the report was informational and moved that it be accepted. Dr Phippen seconded the motion, and it was so voted.

*Committee on Postgraduate Assembly*—Dr Leroy E. Parkins, Suffolk, Chairman

The report of the committee is as follows:

On October 29, 30 and 31, 1947, the Sixth Annual New England Postgraduate Assembly was presented with the co-operation of the other state medical societies of New England. The other societies were represented on the Executive Committee by the following: Maine, Dr Fred Erick T. Hill, New Hampshire, Dr John P. Bowler, Vermont, Dr Philip K. Wheeler, Rhode Island, Dr Emory M. Porter, Connecticut, Dr Stanley Weld. A fine spirit of co-operation and helpfulness was evidenced at all times from these representatives in making the Assembly a success.

The program was published in the *New England Journal of Medicine*, issue of October 23, 1947. The committee wishes to express high praise and appreciation of the distinguished group of speakers, who contributed to making the program one of the best that has been presented.

In addition to the usual didactic lectures, clinics in Boston hospitals were held. This was an experiment that was generally very successful so that it will be continued as a feature of the program next year.

All committees of the Assembly deserve the thanks of the Society, also we wish to express our thanks to Mr Boyd who handled the details of business management.

The attendance of physicians for 1947 was 744 (for 1946, 488). The income from booths was \$3,045 and that from registration was \$2,546; the total income was \$5,591. The total expenses as of December 1, 1947, were \$4,917.82. The net profit was \$673.18.

On account of the necessity of reserving hotel space a year or more in advance to ensure choice of dates, the committee makes the following recommendation that a New England Postgraduate Assembly be held in 1948, 1949 and 1950 on the present basis of organization or until such time as the respective societies vote changes and that the dates for the 1948 meeting be November 3, 4 and 5.

Dr Parkins moved acceptance of the report. Dr Bearse seconded the motion, and it was so voted unanimously.

Dr Parkins stated that there was one recommendation that the Assembly be held in 1948, 1949 and 1950 on the present basis of organization or until such time as the respective states vote changes, and that the dates for the 1948 meeting be November 3, 4 and 5. Dr Parkins moved the adoption of this recommendation. Dr Richard M. Smith seconded the motion, and it was so voted.

*Committee on Legislation*—Dr George R. Dunlop, Worcester, Chairman

Dr Dunlop presented the report of the committee, as follows:

At its last meeting on October 1, special powers were again delegated to the Executive Committee of the Committee on Legislation. Mr Charles Dunn was reappointed as legislative counsel. It was voted to submit a budget of \$5,000 to the Committee on Finance.

Dr Dunlop called attention to a bill (H 104) submitted by the Massachusetts Department of Health that he considered important. In 1946 the Hospital Survey and Construction Act became federal law, and under it each state is required to delegate an agent to conduct a survey of the state's needs. To date forty-one states have passed legislation designating the agent. All but nine have designated the state department of health. H 104 designates the department of health as the agent. From a questionnaire sent to all state governors, United States Senator Smith found that Utah was the only state favoring the Wagner-Murray-Dingell Bill.

Dr Dunlop moved acceptance of his committee's informational report.

Dr Lester M. Felton, Worcester, asked if the Committee on Legislation favored H 104. Dr Dunlop said that the executive committee of the committee favored the bill.

Dr Butler pointed out that the Wagner-Murray-Dingell Bill also provides for grants in aid to states initiating health programs.

Dr Bagg requested Dr Conlin to say something about the Nolen-Miles Pound Bill (S 264).

Dr Conlin stated that there were six anti-vivisection bills to be acted upon this year. Material on S 264 appeared in the *New England Journal of Medicine*, issue of February 12. Material is being mailed to the speakers' bureau in eighteen districts, to the Women's Auxiliaries and to the press. The supply of animals is growing increasingly smaller, and this situation has become so acute that the bill is introduced with an emergency preamble to make it possible to obtain more animals at once.

Dr Conlin stressed the importance of unanimity among the members of the Society in this matter and stated that he wished to offer a resolution.

Dr Bagg brought up the point that since the resolution was not in the committee report, the rules would have to be suspended by vote of the Council before action could be taken.

It was so moved and seconded and voted unanimously to suspend the rules. Dr Conlin then introduced the following resolution:

Whereas benefits of inestimable importance have derived from animal experimentation of value to both men and animals; and Whereas the continuation of animal experimentation is a matter fundamental to teaching and research in the medical sciences; Be it resolved by the members of the Council of the Massachusetts Medical Society assembled in Boston on February 4, 1948, that all efforts to restrict humane animal experimentation will be opposed and efforts to make animals from public pounds available for medical teaching and research will be given the strongest possible support.

Dr Bagnall seconded the motion, and it was voted unanimously, followed by applause.

Dr Dunlop moved acceptance of the report Dr Fitz seconded the motion, and it was so voted

Dr Bagg asked the Secretary to read a communication from the chief medical officer of the regional office of the Veterans Administration to Dr Humphrey L McCarthy, chairman of the Committee on Veterans Affairs, under suspension of the rules Dr Gallupe read the letter (Appendix No 8)

Dr Fitz moved that this letter be accepted as the report of the committee Dr Bagnall seconded the motion, and it was so voted

Dr Ober moved to remove the suspension of the rules The motion was seconded and it was so voted

### NEW BUSINESS

Dr Bagg stated that the Executive Committee voted to approve Dr Kickham's motion to refer matters similar to the Gallupe Plan to the Committee to meet with the Massachusetts Hospital Association.

Dr Bagnall moved to approve the motion The motion was seconded, and it was so ordered by vote of the Council

Dr Bagg said that he had received a letter from Dr Howard B Sprague, president of the New England Heart Association, asking for approval of the campaign of the National Heart Association by the Council, the Executive Committee had voted approval

Dr Hornor moved that the Council approve the campaign Dr Fitz seconded the motion, and it was so voted

Dr Bagg stated that the same letter requested a contribution from the Society and that the Executive Committee had voted to take no action on the request

Dr Fitz moved that the Council approve the action of the Executive Committee Dr Bagnall seconded the motion, and it was so voted

Dr Bagg said that Dr Sisson had written a letter to him indicating that news releases from studies on child health care in the United States might be food for thought for the Society, that Dr Curley had moved that the matter be referred to the Committee on Medical Education and that the Executive Committee had so voted

Dr Sisson moved that the Council approve this action Dr O'Hara seconded the motion, and it was so ordered by vote of the Council

Dr Ohler, Norfolk, recalled to members of the Council that, as a part of its wartime activities, the management of the Bureau of Clinical Information had been given to the Committee on Postgraduate Medical Education That committee now recommended that control of the Bureau be taken over by the Secretary as an integral part of the central office of the Society

Dr Bagg stated that under the rules he would refer the matter to the Executive Committee for action at the next meeting of the Council

Approval of this action was moved and seconded and so ordered by vote of the Council

Dr Bagg then said that Dr Getting wished to introduce a resolution Dr Vlado A Getting, Middlesex South, spoke as follows

Because of the urgency required in acting upon this resolution, the Massachusetts Department of Public Health and the American Red Cross have not been able to bring this matter to the attention of the Society in the usual manner This morning I had a conference with Dr Diamond, who is the new technical director of the American Red Cross and who has just returned from Washington

As you know, for the past two years the Department of Public Health has been conducting a program for the free distribution of whole blood and blood fractions to the people of the Commonwealth In June, 1947, the American Red Cross voted on and adopted a policy of making such products available to all the people of the nation

After repeated conferences, including representatives of the American Red Cross and the Commonwealth, and after clearance with the Governor and other officials, it has been the determination of the Department of Public Health that the best policy to adopt in Massachusetts was not to continue this program from tax funds, as we have in the past, which would involve an annual expenditure of between one-quarter and one-half million dollars, but to take this responsibility to the Red Cross and request the Red Cross to assume the responsibility for continuing the Massachusetts blood program

This will mean that our laboratory will still continue and will probably be used by the American Red Cross as a research center, and as a center for processing of some fractions It is hoped that on or about March 1 and certainly by July 1, the collection, distribution and processing of whole blood will become a responsibility of the American Red Cross, provided, however, that the Massachusetts Medical Society endorses in principle this transfer

I, therefore, suggest the following motion

I recommend that the Massachusetts Medical Society approve in principle the transfer of the program for the provision of whole blood and blood fractions from the Massachusetts Department of Public Health to the American Red Cross, with the understanding that this Society and the Massachusetts Department of Public Health will serve in an advisory and consultative capacity to the American National Red Cross in this program

Dr Getting then moved for suspension of the rules to have a vote on the recommendation Dr Bagnall seconded the motion

The President then stated that Dr Ohler's motion was urgent, and that if permitted he wished to include Dr Ohler's resolution under suspension of the rules

The motion to suspend the rules was so voted unanimously

Dr O'Hare, Suffolk, suggested to Dr Getting that his resolution ought to read "approved by the Council of the Society"

Dr Getting accepted the suggestion and moved acceptance of the resolution Dr Ober seconded the motion, and it was so voted

Dr Bagg then asked for approval of Dr Ohler's resolution It was so voted by the Council

Dr Ober, Suffolk, offered the following motion

a) that a committee of five be appointed by the president of the Society to study the recommendations of the Fee Committee, first, with regard to aid to physicians

who are incapacitated through no fault of their own, and second the assisting of widows and orphans of physicians.

b) that this committee present a working plan or plans to this Council, which will implement the recommendations of the Fee Committee.

The motion was seconded, and it was so ordered by vote of the Council.

Dr David Halbersteden, Norfolk, then spoke.

Because of the passage by the Council last fall or the adoption of the report of the McKittick committee and also because of the apparent failure of the Blue Cross to include recommendations in the contract currently under discussion I wish to present two resolutions for consideration and for action under suspension of the rules. The first resolution is as follows:

Whereas the Council of the Massachusetts Medical Society is concerned with the provision now and in the future of the best possible medical care of the people of the Commonwealth and believes that the recommendations of its special committee (sometimes referred to as the McKittick Committee) in avoiding exploitation of the patient, the hospital or the physician is an important factor in the provision of such care, be it Resolved that the Council advise the staff members of hospitals within the Commonwealth to discuss and arrange with the directors and trustees of such hospitals the best ways for promptly carrying out the aforementioned recommendations and that copies of this resolution and of the part of the McKittick Committee be promptly transmitted to the trustees of the Massachusetts Hospital Association and to the directors of the hospitals of the Commonwealth.

After Dr Bagg had said that he thought the matter had already been covered by previous action, the motion was seconded but failed to carry on a show of hands.

Dr Halbersteden then offered the following resolution, for consideration under suspension of the rules.

Whereas the Council of the Massachusetts Medical Society is interested and concerned with the welfare and healthy continuance of the nonprofit insurance plan for hospital care for the people of the Commonwealth, be it Resolved that the Council of the Massachusetts Medical Society suggest to the Directors of Massachusetts Hospital Service, Inc. and to the members of the Massachusetts Hospital Association that this aim can be best achieved by a fair and equitable reimbursement of each and every hospital by a uniform fee for each day of hospital care and by the elimination of payments to any hospital for administration of anesthesia and interpretation of laboratory and x-ray findings because these are professional functions better provided for by insurance for professional services and that.

The Council urge the Directors of the Massachusetts Hospital Service to include these suggestions in the contract currently under consideration and that copies of this resolution be promptly transmitted to the Insurance Commissioner of the Commonwealth, the Trustees of the Massachusetts Hospital Service, Inc., and to the Trustees of the Massachusetts Hospital Association.

Dr Bagg then read a note from the directors of Blue Cross to the effect that although x-ray service and anesthesia will remain in the contract, a differential charge will be allowed for all services to patients in private accommodations.

The motion was seconded.

After discussion by Dr Bagnall and Dr McKittick, Dr McKittick moved that the matter be laid on the table. The motion was seconded, and it was so ordered by vote of the Council.

Dr Ober moved that the rules be suspended. The motion was seconded, and it was so voted.

Dr Bearse moved that the by-laws be amended by the addition of another standing committee, to be known as the Committee on Constitution and By-Laws.

Dr Hornor moved as an amendment that the president of the Society be requested to appoint a committee of three to report to the Executive Committee on what ought to be done about by-laws.

Dr Bearse accepted the amendment.

It was moved and seconded that the matter be laid on the table. On a show of hands the motion to table was carried.

Dr Bagg suggested that a motion to adjourn was in order. The motion was made, seconded and so voted at 110 p m.

H QUIMBY GALLUPE, Secretary

## REPORT OF COMMITTEE ON FINANCE — BUDGET FOR 1948 (Concluded)

		SPECIAL COMMITTEES	
3,750 00	3,369 00	Bureau of Clinical Information	
—	—	Cancer	3,500 00
365 00	357 00	Fee Schedule	50 00
200 00	166 00	Malpractice Insurance Study	50 00
75 00	64 00	Medical Economics	200 00
1,000 00	—	New England Postgraduate Assembly (Income over expenses \$1,016)	—
3,750 00	2,913 00	Postgraduate Education (Income \$2,358)	1,000 00
335 00	181 00	Postwar Loan Fund	3,500 00
—	71 00	Rehabilitation	—
—	30 00	School Medical Services	—
—	361 00	Special Services	75 00
			300 00
		OTHER EXPENDITURES	
4,000 00	4,000 00	Refund to District Medical Societies	8,000 00
100 00	100 00	Dues Council New England State Medical Societies	—
—	5,000 00	To carry <i>New England Journal of Medicine</i>	10,000 00
—	4,233 80	Premium payment pension plan (Mr. Boyd)	4,014 00
—	507 58	Tax expense (Social security and unemployment insurance, newly required by Bureau of Internal Revenue)	670 00
—	—	Contingent fund to cover (approximately) expenses of Director of Medical Information and Education and possible change in salary of Secretary	9,200 00*
\$64,070 00	\$67,220 38		\$86,359 00

\*Amount of Secretary's salary contingent upon possible change to full-time status budget of Director of Medical Information and Education.

†Anticipated expense of delegates to two A. M. A. meetings carries over into 1948, as second meeting was not held until January, 1948.

‡Added expense due to request of A. M. A. for delegates to Cleveland meeting in January, 1948.

§The 1947 budget of the Publications Committee included \$2,000 for publication of directory and \$5,000 to carry *New England Journal of Medicine*. The Committee has requested authority to increase the latter figure to \$10,000.

## ESTIMATED INCOME

Annual dues	1947	1948	(not including \$10 allocation to Bureau of Medical Library)
Non resident dues	\$54,450 00	\$108,900 00	
Censors' fees	2,230 00	2,200 00	
General Fund income	1,250 00	1,250 00	
Committee on Arrangements	5,200 00	5,200 00	
Postgraduate Assembly	6,000 00	4,000 00	
Profit on sale of securities	1,000 00	700 00	
From <i>New England Journal of Medicine</i>	770 00	600 00	
	\$70,900 00	\$122,850 00	

## APPENDIX NO 6

## REPORT OF THE COMMITTEE ON CANCER

A meeting of the committee was held on November 28, 1947.

The problem of cancer-detection clinics in general, and the proposed cancer-detection clinic at the Palmer Memorial Hospital in particular, were discussed. Critical analysis of the functions of a cancer-detection clinic as ordinarily set up shows that the objective of attempting to give the entire population periodic examinations to detect early cancer is impossible, both because of insufficient personnel (for example, it is estimated that it would take all the radiologists in the country a year to give the population a gastrointestinal x-ray series alone) and because of the tremendous cost (over one and a quarter billion dollars a year). Nonetheless, these clinics, largely fostered by lay organizations such as the American Cancer Society and the Donner Foundation, have become tremendously popular and some four hundred are in existence at the present time. At least forty states have clinics of this type.

The American Medical Association and the American College of Surgeons have recognized that there is much of value in these clinics and have laid down certain principles for their establishment and operation. In its recommendation made to the Council at the October meeting the Cancer Committee did not make clear certain important points in which the proposed cancer-detection clinic at the Palmer Memorial Hospital would differ from most of those already established.

This clinic is not planned simply as an addition to the four hundred already established in the country, in spite of the great popular demand for a clinic of this type. It is planned not merely to fulfill the function of finding early cancer in a limited number of patients or of assuring them that they have no sign of the disease. Rather, and far more important, it is aimed primarily at determining procedures of special value in detecting cancer that may be applied by the physician in private practice and at serving as a demonstration center for such procedures.

It is recognized that the best and most effective type of cancer detection should be the work done by the individual practitioner of medicine with his own patients. However, a great number of procedures that might be used in the doctor's office are perhaps not calculated to yield results commensurate with the time, expense and detail involved. The proposed cancer-detection clinic would serve as a proving ground for different types of diagnostic methods and as a center where doctors might come to determine procedures applicable to the problems of their own practice. A number of physicians have neither the time nor the equipment to give the type of examination they consider a person coming to them to determine the presence or absence of cancer should have, and a facility of this type to which they could refer such persons has definite value.

The work of the general practitioners would be augmented by the increased number of cases referred to him for management and treatment. It is desirable that patients accepted by the clinic should be referred by their physicians. In many cases there may be persons who have no family physician and who might therefore be accepted for examination. In all cases, reference for treatment will be made to the physician of the patient's choice.

The relation of such a cancer-detection clinic to the already existing cancer clinics and tumor clinics throughout the Commonwealth has been carefully considered. Since the cancer and tumor clinics are planned for the patient who has a lesion, cancerous or noncancerous, and the cancer-detection clinic is for the person who considers himself well, there can be no conflict. Moreover, the cancer-detection clinic does not attempt therapy in any form.

The question has been raised whether such a clinic might not better be supported in part by voluntary gifts rather than by state or federal funds. This question is an entirely proper one, and it is believed that the support of such a clinic might better come from voluntary gifts if available than from state or federal sources. In the present instance, however, public funds are at hand, and voluntary funds are not. If voluntary funds cannot be readily obtained, public funds should be accepted.

who are incapacitated through no fault of their own, and second the assisting of widows and orphans of physicians b) that this committee present a working plan or plans to this Council, which will implement the recommendations of the Fee Committee

The motion was seconded, and it was so ordered by vote of the Council

Dr David Halbersleben, Norfolk, then spoke

Because of the passage by the Council last fall, or the adoption of the report of the McKittick committee, and also because of the apparent failure of the Blue Cross to include recommendations in the contract currently under discussion I wish to present two resolutions for consideration and for action under suspension of the rules. The first resolution is as follows:

Whereas the Council of the Massachusetts Medical Society is concerned with the provision now and in the future, of the best possible medical care of the people of the Commonwealth and believes that the recommendations of its special committee (sometimes referred to as the McKittick Committee) in avoiding exploitation of the patient, the hospital or the physician is an important factor in the provision of such care be it Resolved that the Council advise the staff members of hospitals within the Commonwealth to discuss and arrange with the directors and trustees of such hospitals the best ways for promptly carrying out the aforementioned recommendations, and that copies of this resolution and of the part of the McKittick Committee be promptly transmitted to the trustees of the Massachusetts Hospital Association and to the directors of the hospitals of the Commonwealth

After Dr Bagg had said that he thought the matter had already been covered by previous action, the motion was seconded but failed to carry on a show of hands

Dr Halbersleben then offered the following resolution, for consideration under suspension of the rules

Whereas the Council of the Massachusetts Medical Society is interested and concerned with the welfare and healthy continuance of the nonprofit insurance plan for hospital care for the people of the Commonwealth be it Resolved that the Council of the Massachusetts Medical Society suggest to the Directors of Massachusetts Hospital Service Inc., and to the members of the Massachusetts Hospital Association that this aim can be best achieved by a fair and equitable reimbursement of each and every hospital by a uniform fee for each day of hospital care and by the elimination of payments to any hospitals for administration of anesthesia and interpretation of laboratory and x-ray findings because these are professional functions better provided for by insurance for professional services and that

The Council urge the Directors of the Massachusetts Hospital Service to include these suggestions in the contract currently under consideration and that copies of this resolution be promptly transmitted to the Insurance Commissioner of the Commonwealth the Trustees of the Massachusetts Hospital Service Inc. and to the Trustees of the Massachusetts Hospital Association

Dr Bagg then read a note from the directors of Blue Cross to the effect that although x-ray service and anesthesia will remain in the contract, a differential charge will be allowed for all services to patients in private accommodations

The motion was seconded

After discussion by Dr Bagnall and Dr McKittick, Dr McKittick moved that the matter be laid on the table. The motion was seconded, and it was so ordered by vote of the Council

Dr Ober moved that the rules be suspended. The motion was seconded, and it was so voted

Dr Bearse moved that the by-laws be amended by the addition of another standing committee, to be known as the Committee on Constitution and By-Laws

Dr Hornor moved as an amendment that the president of the Society be requested to appoint a committee of three to report to the Executive Committee on what ought to be done about by-laws

Dr Bearse accepted the amendment

It was moved and seconded that the matter be laid on the table. On a show of hands the motion to table was carried

Dr Bagg suggested that a motion to adjourn was in order. The motion was made, seconded and so voted at 1 10 p m

H QUIMBY GALLUPE, Secretary

President Bagg presented Dr Channing Frothingham, a former president of the Massachusetts Medical Society, who was present at Dr Bagg's invitation to speak on the National Physicians Committee, inasmuch as he had not been given an opportunity to do so at the last meeting of the Council

The discussion regarding the National Physicians Committee arose in consequence of the fact that the Committee on Public Relations, at its last meeting, recorded itself as approving the objectives of this committee. Dr Daniel B Reardon and Dr John F Conlin stated that they had been present at the September meeting of the National Physicians Committee and were very favorably impressed with the work of this committee, especially by the factual presentations and discussions and the absence of high-pressure salesmanship. It was stated that there were two different groups

One group received its financial support mostly from physicians and concerned itself entirely with medical problems, particularly with socialized medicine as it manifested itself in the Wagner-Murray-Dingell Bill

The second group was mainly supported by institutional grants and was interested chiefly in educational and research problems, such as the communistic influences in educational and political structure

It is the opinion of the National Physicians Committee that socialized medicine could be the keystone for a communistic state. Drs Reardon and Conlin believed that the objectives of the National Physicians Committee could be approved so far as this committee concentrated its effort in the defeat of the Wagner-Murray-Dingell Bill

It was Dr Frothingham's contention that many of the facts presented by the National Physicians Committee were erroneous and debatable, and that the true facts concerning this committee should be presented to the members of the Council before any final action could be taken concerning the endorsement by the Council of the objectives of this committee

Dr Howard Root, Suffolk, made a motion that Drs Conlin, Reardon and Frothingham meet with the Committee on Medical Economics and present to the next meeting of the Council facts concerning the National Physicians Committee, presenting such arguments, for and against the controversial issues, as may arise with reference to the work and objectives of this Committee

Dr Conlin emphasized the necessity of some directive by the Massachusetts Medical Society about the attitude of the Society toward the National Physicians Committee, inasmuch as he has been constantly questioned

The motion was carried

Dr N S Scarcello's resolution, which had been sent back to the Public Relations Committee by the Council (namely "That the Blue Shield, through its employees, determine accurately an applicant's yearly earnings before issuing a policy, and secondly, that these earnings be reviewed each year") was returned to Dr Charles D McCann's Subcommittee on Blue Cross-Blue Shield Problems

Dr S A Dibbins, Middlesex North, stated that in Lowell patients hospitalized because of diagnostic problems could not have their bills paid as members of the Blue Cross, but the same patients, if they were admitted to the Pratt Diagnostic Clinic, had their bills paid by the Blue Cross

It was suggested by President Bagg that this criticism of the Blue Cross be sent to Dr Charles D McCann's special subcommittee for further investigation

Dr N S Scarcello, Worcester, expressed the opinion that the members of the Massachusetts Medical Society were not adequately informed concerning the financial status of the Blue Shield inasmuch as the members are responsible and liable for this corporation. President Bagg agreed with Dr Scarcello's opinion and requested Dr Scarcello to notify him personally, in writing, to this effect

The following letters were received by the Secretary and were presented merely as matters of information. From Dr Brendan D Leahey, secretary of Middlesex North District Medical Society, the following

At the last meeting of the Middlesex North District Medical Society, there was considerable discussion of Blue Shield fees. Many of the members resented the fact that the Blue Cross rates to the subscriber were raised to allow greater payments to the hospitals but the Blue Shield

## APPENDIX NO 2

## REPORT OF THE COMMITTEE ON PUBLIC RELATIONS

A meeting of the committee was held on November 12, 1947. In addition to representatives of nine district societies the following were present: President Edward P Bagg, who acted as chairman of the Committee, Dr Daniel B Reardon, president-elect, Dr H Quimby Gallupe, secretary of the Society, Dr John F Conlin, Director of Medical Education and Information, and Mr Robert St B Boyd, executive secretary

rates were left unchanged. It was unanimously voted that "The Middlesex North District Society shall go on record as favoring an increase to the basic rates of the Blue Shield paralleling that of the Blue Cross so that payments to physicians may be increased."

This action is to be brought to the attention of the Executive Committee of the Massachusetts Medical Society. It was also suggested that all other district societies be informed of our views in this matter with the hope that they will discuss the situation and take appropriate action.

A letter from Dr. Bernard Appel, Essex South, was then read, stating that the medical staff of the Salem Hospital was unanimously opposed to the inclusion of professional services in the Blue Cross policy.

Dr. Appel wished that this information be conveyed to the special Subcommittee on Blue Cross-Blue Shield Problems. These matters were turned over to Dr. McCann's special Subcommittee on Blue Cross-Blue Shield Problems.

Dr. John F. Conlin gave a general summary of the work of the Director of Medical Education and Information. He stressed the value of public relations to the individual physicians as well as to society at large. He discussed the occasional necessity of accepting invitations to speak to various groups in the districts and believed that courtesy clearances could be obtained from the local public relations councilor or the district officers that the district could be kept informed of his local speaking engagements. He furthermore stressed the importance of his liaison professional activities with various groups, especially the legal group, and mentioned the advisability of joint meetings at state level such as those being held at the Malden Hospital and under the auspices of the Suffolk District Medical Society.

He reported as having given a talk on interprofessional co-operation to the Metropolitan District Dental Society and stated that talks of a similar nature are being booked with nurses, optometrists and chiropractors. These discussions are bringing an excellent response and improved public relations.

'Career Day,' as sponsored by the Exchange Club of Needham for the students of the Needham High School was reported. At that time a general report on the choice of a career was given all students. A number of professional men and representatives from business, trade, industry and so forth presented the pros and cons of their occupations to groups of students. Dr. Conlin presented medicine and was impressed by the interest and questions of the students.

There was also reported numerous appearances by Dr. Conlin before various commissions and State House committees. He stated that there was a marked interest in education in health and in the attitude toward health examinations in school. Joint conferences are being planned with school superintendents, teachers, health educators and school physicians.

With reference to the radio programs Dr. Conlin mentioned the Saturday morning program given at 11:30 for half an hour by five Boston hospitals, 'Medical Center of the Air,' which was given with Society approval.

The new program, 'Doctor's Orders,' which is being given at 1:15 p.m. on Sundays with combined dramatizations and pertinent physician interviews is going over quite well. Scripts have been furnished for two of these six monthly broadcasts over WHAV in Haverhill. A new series of scripts slanted at the animal-experimentation background of medical research is now in hand.

Press releases are being planned to keep the public informed of the Society's interest in health and health education. Newsletters are very much desired to keep all the members of the Society informed concerning legislative matters and other activities of the Society. This goes a long way toward building better and stronger internal relations, which are so necessary to satisfactory public relations.

It is furthermore hoped by Dr. Conlin to arrange several public forums about six in number on medical topics. These are to be presented in Greater Boston and without charge as a public service feature. If hall and speaker co-operation can be obtained.

Dr. Conlin further reported that the Society headquarters facilities are being used to an increasing extent by members

seeking information. Requests for speakers are increasing and the Speakers' Bureau is making slow but favorable progress.

Better Business Bureaus are showing interest in ethical advertising practices pertaining to medicine.

With reference to the Women's Auxiliaries, Dr. Conlin reported that Norfolk and Suffolk districts are organized with other districts as Essex South and Middlesex South in the process of organizing.

Mention was also made by the Director of Medical Education and Information that a number of physicians, many of them graduates of approved schools, were unable to obtain hospital-staff appointments. A few complaints have been received from veteran physicians experiencing difficulty in returning to appointments previously held. The matter is under study and survey data will be accumulated.

Dr. Conlin also received the following letter from the Massachusetts State Nurses Association:

One of the current activities of the Massachusetts State Nurses Association through its public relations committee is the preparation of a Fact Sheet on schools of nursing in Massachusetts. The material is ready to go to the printer.

The recruitment of students for schools of nursing is an interest of other groups as well as of the nursing organization. Already the Massachusetts Hospital Association and the Massachusetts League of Nursing Education have endorsed the Fact Sheet and are helping to underwrite a portion of the cost. We feel the Massachusetts Medical Society also might be interested to a similar extent and make available to its members the Fact Sheet for information and distribution. For it is a known fact that young women turn to their family physician for advice about nursing schools.

The estimated cost for printing 10,000 copies of the Fact Sheet is \$200. Would the Massachusetts Medical Society consider \$50 toward the cost of printing?

We would appreciate a favorable consideration of this matter that we might include the name of the Massachusetts Medical Society with the other organizations as publishers of the Fact Sheet.

HELEN G. LEE, Executive Secretary

The Committee on Public Relations recommended the expenditure of the \$50.

Dr. Conlin again emphasized his willingness to co-operate with the district societies in initiating the women's auxiliary groups.

President Bagg stated the request of Former President Elmer Bagnall that this committee express an opinion about taking out additional subscriptions of the Marjorie Shearon Medical Legislative Service in Washington. This would necessitate an increase of the subscription fee from \$200 to \$500. This received the endorsement of the Committee on Public Relations with the request that the members of the committee receive a copy of the Service.

This report was approved.

The meeting was adjourned at 7:00 p.m.

HAROLD R. KURTZ, Secretary

## APPENDIX NO. 3

### NATIONAL PHYSICIANS' COMMITTEE

The National Physicians Committee was organized in 1939 as a nonprofit organization to speak for the American Medical Association in an interim if a court decision was unfavorable. After the litigation in the Washington case died down it was the opinion that such an organization outside organized medicine could do many things in the field of public education and legislative representation that might be helpful.

The principal object of the National Physicians Committee is to bring about an appreciation on the part of the general public of the outstanding medical care that has been received under the private practice system and by all means to emphasize that particular point.

The National Physicians Committee is like a public relations councilor employed to educate the general public. It has succeeded in bringing about a realization that if medicine and the administration of health care services are

brought under federal control, it will be only a short step until all business will be directly controlled by the federal Government

The policies of the National Physicians Committee are decided by a board of trustees well known to the medical profession. At the centennial meeting of the American Medical Association a reference committee gave final recommendation to the efforts of the National Physicians Committee in spite of the fact that the American Medical Association itself had expanded its public-relations program.

Through the efforts of the National Physicians Committee on a go-ahead from the American Medical Association the little Wagner-Murray-Dingell Bill in Hawaii has been defeated during the past year.

The National Physicians Committee was active during the Seventy-Ninth Congress, and twenty-seven out of thirty-five volumes of testimony on the health-service bill include attacks on the National Physicians Committee by those most interested in the passage of the compulsory health legislation.

The National Physicians Committee does not maintain that all those in favor of compulsory health insurance are communists or belong to the Communist Party, but it does maintain that socialization of health care services is the keystone of the socialized state.

In the coming hearings the National Physicians Committee has arranged to have Dr. Friedman available for consultation with physician witnesses, and Miss Elizabeth Wilson, of Boston, an expert actuary, will be available as a technical adviser.

## APPENDIX NO 4

### REPORT OF THE EXECUTIVE COMMITTEE

The Executive Committee of the Council met on January 7, 1948, in Sprague Hall, 8 Fenway, Boston, Massachusetts, at 4:00 p.m. The meeting was called to order by President Edward P. Bagge. Present were Dr. Daniel B. Reardon, president-elect, Dr. Elton Hubbard, Jr., treasurer, Dr. H. Quimby Gallupe, secretary, and representatives of all district societies except Barnstable, Berkshire, Bristol South, Middlesex South and Suffolk.

The record of the meeting of September 3, 1947, as presented at the meeting of the Council on October 1, 1947, was submitted by the Secretary and was approved.

### COMMITTEE REPORTS

Dr. Bagge presented the matter of the Blue Shield as discussed at the October Council meeting and read a letter from Dr. N. S. Searcello, Worcester, expressing the opinion that members of the Society were not adequately informed concerning the financial status of the Blue Shield. Dr. Curley, Worcester, reported that the Blue Shield has initiated in Worcester County a method by which the participating physicians notify the Blue Shield instead of going through the Blue Cross. The patient initiates the upper part of the notice, and the physician completes it when the patient has left the hospital. It is sent to Blue Shield and the doctor should be paid in ten days or less. The income of the patient is discussed by doctor and patient in the office. Worcester District Medical Society recommends that the fees of general surgery should be increased. Blue Shield has a low administrative cost (8 per cent), ordinary insurance-company costs run to 30 or 40 per cent. Dr. Curley asked whether the subcommittee was running Blue Shield or whether the Executive Committee was running it. Dr. Bagge explained that the Executive Committee is too unwieldy to work on the matter, that he expected the subcommittee to report at the annual meeting, and that the Executive Committee would finally act.

Dr. Curley moved to approve the following changes in the by-laws suggested in a letter from Dr. Bagnall as requested by Dr. Bagge:

"Referring to the by-laws, Chapter IV, Section I, in line 5, strike out the word 'and,' inserting a comma there instead, after the word 'committees' inserting a comma instead of a period, and then adding the following words 'with the Medical Director of the Massachusetts Medical

Service, Inc., and the President of the Massachusetts Medical Service, Inc., if he be a member of the Society."

This motion was seconded by Dr. Wheeler and put to a vote and unanimously carried.

Dr. Bagge then presented Mr. Peterson, representing the National Physicians Committee, who described what the committee had done, what its objectives are, and what had been accomplished so far. Dr. Appel, Essex South, pointed out that no action concerning the approval or disapproval of the work of the National Physicians Committee could be taken because the committee consisting of Drs. Reardon, Conlin and Frothingham had made no report. Dr. Conlin reported that no meeting of that committee had been held. Dr. Bagge then ruled that no action could be taken until that subcommittee reported.

### Committee on Publications

Dr. Dame moved that the report of this committee as published in the circular of advance information be accepted. Dr. Wheeler seconded the motion. The motion was carried.

Dr. Curley moved to sponsor the resolution that the editor of the *Journal* should *ex-officio* be a member of the Council. Dr. Wheeler seconded the motion. The motion was voted unanimously.

Dr. Smith pointed out that the *Journal* this week reached 25,000 copies, the highest in its history.

### Committee on Arrangements

This report was accepted as informational. Dr. Bagge reported that he had obtained Mary Ellen Chase, head of the Department of English literature at Smith College, as the speaker at the annual dinner.

### Committee on Finance

This committee voted unanimously that the salaries of two office employees be increased to \$40 per week retroactive to January 1, 1948. (These words do not appear in the printed report of the committee but the figures in the budget are on line 16, page 13 of the circular of advance information.) The report of this committee was accepted unanimously.

### Committee on Cancer

Dr. Bagge ruled that the report of this committee presented at the October 1 meeting of the Council be taken from the table. Dr. Wheeler so moved. It was seconded and voted.

It was then moved that the first and second reports of the committee be accepted. This motion was voted and carried.

It was then moved and seconded that the Council approve in principle the establishment of a cancer-detection clinic at the Palmer Memorial Hospital. This motion was voted unanimously. It was then moved and seconded that the report as a whole be accepted. The motion was voted and carried unanimously.

### Postwar Loan Fund Committee

Dr. Hubbard moved that the report be accepted and the committee be discharged. Dr. Wheeler seconded the motion, which was voted and carried unanimously.

### Committee on Malpractice Insurance

Dr. Bearse read the report as printed and moved acceptance. Dr. Curley seconded the motion, which was voted and carried.

### Report of the Committee of Seven

Dr. Fitz read and emphasized parts of the report. He also pointed out that on page 20, line 22, the word "standing" should be deleted. Dr. Fitz then moved the acceptance of this report with the one change mentioned above. Dr. Curley seconded the motion, which was voted and carried unanimously.

Dr. Fitz pointed out that the committee had further duties and submitted the following supplementary report:

The committee recommends that a basic salary of \$10,000 a year be accepted as proper for a secretary who devotes his entire time to the work of the Society, such

basic salary to be adjusted from year to year by the Council in such fashion as the Council deems proper.

Under authority granted by the Council at the stated meeting on October 1 1947 the Committee has arranged with Dr. Gallupe, now secretary, to devote as much of his time as possible to the work of this office until his successor is elected. The committee estimates that he will spend at least two thirds of his time for the benefit of the Society between now and the annual meeting. The committee therefore has ordered the Treasurer to pay him from January 1 1948 until the annual meeting at the rate of \$550 per month this figure being approximately two-thirds of the monthly stipend that would be paid to a secretary receiving \$10 000 a year.

Dr. Fitz then moved that the Executive Committee approve the action of the Committee of Seven. Dr. Curley seconded the motion which was carried unanimously.

#### *Report of the Advisory Council to the Women's Auxiliary*

This report was adopted as one of progress.

#### *Committee on Public Health*

This report was adopted as one of progress.

#### *Committee on Postgraduate Assembly*

It was moved and seconded that the recommendation beginning on line 5 page 22 be adopted. The motion was carried.

#### *Committee on Legislation*

This report was adopted as printed.

### NEW BUSINESS

Dr. Charles J. E. Kiekham, Norfolk, stated that the councilors of the Norfolk District Medical Society had voted to request him to move that the Executive Committee approve a new committee on hospital relations to which might be referred matters like the Gallupe Plan. Dr. Bagg suggested that there are now two committees on hospitals. Dr. Appel seconded Dr. Kiekham's motion. Dr. Dame moved to amend the motion to the effect that if the function could be taken care of by a present committee there would be no need of a new committee. Dr. Kiekham stated that he wished to add specifically the relation of the hospital to the Gallupe Plan.

Dr. Bagg then stated the motion as he understood it as follows: "Unless one committee can be found already in existence that a new committee be appointed to further the relations of hospitals to the Society with special attention to the Gallupe Plan."

This motion was seconded, voted and carried.

Dr. Bagg read a letter Dr. Howard Sprague asking for Society endorsement on the campaign of the National Heart Association. It was moved and seconded that such endorsement be recommended to the Council. The motion was carried.

Dr. Bagg pointed out that the Society had no authority to appropriate money to any such drive as that of the National Heart Association. It was moved and seconded to take no action on this request.

Dr. Bagg read a letter from Dr. Sisson indicating that news releases from studies on child health care in the United States would be food for thought for the Society. Dr. Curley moved that the matter be referred to the Committee on Medical Education. The motion was carried.

The meeting was adjourned at 6:15 p.m.

H. QUIMBY GALLUPE, Secretary

## APPENDIX NO 5

### REPORT OF THE COMMITTEE ON FINANCE

The committee met December 3 1947 to consider the budget of the Society for the year 1948. The budget agreed upon is presented herewith. The figures for expenditures during 1947 are only approximate being based upon the

Treasurer's records for the first ten months of the year. In addition to estimates for the remaining two months. The major increases and variations are explained in the footnotes. Action by the Council is requested on several of these changes.

The Committee recommends that the appropriation to carry the *New England Journal of Medicine* be increased from \$5 000 to \$10 000.

The following is from a letter received by the committee from the chairman of the Committee on Publications, Dr. Richard M. Smith:

The cost of materials and all other things is constantly rising and we cannot estimate exactly our budget for 1948. To cover emergencies we request an appropriation of \$10 000 from the Society. We hope very much that it will not be necessary to use this money but to be on the safe side we think we shall need the appropriation available for emergencies. We shall probably be able to return to the Society most of the \$5000 of this year's appropriation.

The Committee further recommends that the *New England Journal of Medicine* shall return to the Society on December 31 any excess of cash over \$10 000 instead of the present amount of \$6000 as agreed upon in 1940.

This recommendation is likewise explained by Dr. Smith as follows:

In 1940 it was agreed that at the end of the year if the *Journal* had any surplus cash over and above \$6000 it should be returned to the Society. This meant, in effect, that the budget of the *Journal* had a working capital of \$6000. At that time the total budget of the *Journal* was very much less than at the present time and we now are somewhat embarrassed by the small working capital. We therefore ask the Committee on Finance to change the arrangement previously made so that the *Journal* shall return to the Society on December 31 any excess of cash over \$10 000 instead of the present amount of \$6000. Our actual expenses for last year were nearly \$250 000 formerly they were well under \$100 000.

The committee recommends that the Council authorize the payment of a federal social security and unemployment tax for 1947 amounting to \$507.58 and that provision for such taxation be made in future budgets.

The necessity for these recommendations is apparent from the following communication received by the committee from the Treasurer of the Society:

The Internal Revenue Department Washington have changed our tax exemption from Code 101 (6) to 101 (7) which still exempts us from federal income tax as a corporation but makes us liable to both social security taxation and unemployment taxation for employees. I consulted with Mr. Dodge the Society's lawyer to see if we should take it lying down and he said: "Yes as the only alternative would be to contest it in court with little prospect of winning."

The committee has set aside a contingent fund of \$5500 in anticipation of a possible increase in salary for the secretary of the Society in case the Committee of Seven should decide that a full time incumbent be elected (as has been proposed) and to cover as well the expenses of the new Bureau of Medical Information and Education. The Committee on Finance is unable to set any exact figure for these two items since no action has as yet been taken that will definitely establish the amount of money required. Action by the Council will enable these figures to be made definite and will no doubt be requested by the appropriate persons.

An estimate of 1948 income prepared by the Treasurer indicates that the Building Fund may be increased by perhaps \$35 000 this year unless expenditures are greater than anticipated in the budget.

ROBERT W. BLOK, Chairman  
FRANCIS C. HALL  
BRYAN PACKARD  
BACROFT C. WHEELER  
CHARLES F. WILKINSKY

## APPENDIX NO 6

## REPORT OF THE COMMITTEE ON CANCER

A meeting of the committee was held on November 28, 1947

The problem of cancer-detection clinics in general, and the proposed cancer-detection clinic at the Palmer Memorial Hospital in particular, were discussed. Critical analysis of the functions of a cancer-detection clinic as ordinarily set up shows that the objective of attempting to give the entire population periodic examinations to detect early cancer is impossible, both because of insufficient personnel (for example, it is estimated that it would take all the radiologists in the country a year to give the population a gastrointestinal x-ray series alone) and because of the tremendous cost (over one and a quarter billion dollars a year). Nonetheless, these clinics, largely fostered by lay organizations such as the American Cancer Society and the Donner Foundation, have become tremendously popular and some four hundred are in existence at the present time. At least forty states have clinics of this type.

The American Medical Association and the American College of Surgeons have recognized that there is much of value in these clinics and have laid down certain principles for their establishment and operation. In its recommendation made to the Council at the October meeting the Cancer Committee did not make clear certain important points in which the proposed cancer-detection clinic at the Palmer Memorial Hospital would differ from most of those already established.

This clinic is not planned simply as an addition to the four hundred already established in the country, in spite of the great popular demand for a clinic of this type. It is planned not merely to fulfill the function of finding early cancer in a limited number of patients or of assuring them that they have no sign of the disease. Rather, and far more important, it is aimed primarily at determining procedures of special value in detecting cancer that may be applied by the physician in private practice and at serving as a demonstration center for such procedures.

It is recognized that the best and most effective type of cancer detection should be the work done by the individual practitioner of medicine with his own patients. However, a great number of procedures that might be used in the doctor's office are perhaps not calculated to yield results commensurate with the time, expense and detail involved. The proposed cancer-detection clinic would serve as a proving ground for different types of diagnostic methods and as a center where doctors might come to determine procedures applicable to the problems of their own practice. A number of physicians have neither the time nor the equipment to give the type of examination they consider a person coming to them to determine the presence or absence of cancer should have, and a facility of this type to which they could refer such persons has definite value.

The work of the general practitioners would be augmented by the increased number of cases referred to him for management and treatment. It is desirable that patients accepted by the clinic should be referred by their physicians. In rare cases there may be persons who have no family physician and who might therefore be accepted for examination. In all cases, reference for treatment will be made to the physician of the patient's choice.

The relation of such a cancer-detection clinic to the already existing cancer clinics and tumor clinics throughout the Commonwealth has been carefully considered. Since the cancer and tumor clinics are planned for the patient who has a lesion, cancerous or noncancerous, and the cancer-detection clinic is for the person who considers himself well, there can be no conflict. Moreover, the cancer-detection clinic does not attempt therapy in any form.

The question has been raised whether such a clinic might not better be supported in part by voluntary gifts rather than by state or federal funds. This question is an entirely proper one, and it is believed that the support of such a clinic might better come from voluntary gifts if available, than from state or federal sources. In the present instance, however, public funds are at hand, and voluntary funds are not. If voluntary funds cannot be readily obtained, public funds should be accepted.

The committee believes that the Council was well advised in deferring action on its report at the October meeting. The intervening time has given opportunity for further study of the problem and for clarification of a number of aspects.

#### RECOMMENDATIONS

It is recommended that the report of the committee presented at the October meeting of the Council be taken from the table.

It is recommended that that and the present report of the Committee on Cancer be accepted by the Council.

It is recommended that the Council approve in principle the establishment of a cancer-detection clinic at the Palmer Memorial Hospital.

SHIELDS WARREN *Chairman*

#### APPENDIX NO. 7

##### REPORT OF THE COMMITTEE OF SEVEN

This committee was appointed to study the need for a full-time secretary and to define the duties of the Secretary, Director of Medical Information and Education and the Executive Secretary of the Society.

In recent years the growth of the Society has been rapid; its interests have broadened and the work of the Secretary's office has increased to so large an extent that the employment of a secretary who devotes his entire time to the work of the Society is urgently needed. The committee recommends that a secretary who devotes his entire time to the work of the Society be henceforward employed.

In defining the duties of the Secretary, the Director of Medical Information and Education, and the Executive Secretary of the Society, the committee believes that certain changes in the By Laws are necessary, therefore the following changes in the By Laws are recommended.

#### BY LAWS

##### CHAPTER IV

##### *Appointment of Director of Medical Information and Education*

**Section 8.** The Council may appoint and dismiss a Director of Medical Information and Education.

##### *Salaries and Appropriations*

**Section 9.** The Council shall vote the salaries of its officers and employees; shall determine the tenure they may respectively have in their offices; the appropriations for its officers, employees and committees; and such other appropriations as it deems suitable.

No officer, employee, or committee shall exceed the voted appropriation.

No salary to any officer or employee and no regular appropriation shall be increased except on recommendation of the Committee on Finance and by vote of the Council.

The Treasurer is authorized on recommendation of the Committee on Finance to pay such monies as may be necessary in the event of emergency, the existence of which shall be determined by the President.

#### CHAPTER VI OFFICERS

##### *Duties of Secretary*

**Section 4.** The Secretary shall attend all meetings of the Society, the Council and the Executive Committee, and shall record their respective proceedings in separate volumes.

He shall cause to be engrossed and shall sign the diplomas of new fellows if satisfied that they have met the requirements of Chapter I and shall issue all diplomas and certificates of fellowship.

He shall notify fellows of votes by the Council or Executive Committee granting permission to retire, to resign, to transfer district membership or to have dues remitted, and of votes depriving them of or reinstating them in the privileges of fellowship.

He shall be *ex-officio* secretary of all boards of trial the Board of Supervising Censors, the Committee on Publications, the Committee on Ethics and Discipline, and the Committee on Membership, and shall keep the records of each in separate volumes. He shall be a member *ex-officio* of all other committees without power of vote.

He shall notify members of committees of their appointment and of the duties assigned them. On advice of their chairman or secretary he shall give due notice of the time and place of their several meetings.

He shall have custody of the seal of the Society and of all books, papers, manuscripts, prints and paintings belonging to the Society, except such as are in charge of the Treasurer.

He shall issue notices of the meetings of the Council according to such rules as the Council may adopt. He shall issue to every fellow one month before the annual meeting of the Society a program listing the time and place of that meeting and of the stated meetings of the Council, the boards of censors for that year and information concerning the payment of assessments and the distribution of publications if there are any proposed amendments of the By Laws, he shall provide that each program is accompanied by a copy thereof.

He shall transfer fellows from one district to another under the terms of Chapter III, Section 3 and shall report to the Society at its annual meeting the changes in membership during the year.

He shall conduct official correspondence and shall notify officers and delegates of their appointments and of their duties.

He shall keep a directory of the fellows and shall publish the same under the direction of the Committee on Publications at such intervals as may be determined by the Council. He shall furnish this on request to fellows not in arrears.

He shall have jurisdiction over the work of the Executive Secretary and over the work of the Director of Medical Information and Education.

##### *Duties of Executive Secretary*

**Section 7.** The Executive Secretary under the jurisdiction of the Secretary shall assist the officers, the Council and such committees as may request his services. He shall also serve as manager of the general office and shall help in the arrangement of the annual meeting and of such other meetings as are sponsored in whole or in part by the Society.

##### *Duties of Director of Medical Information and Education*

**Section 8.** The Director of Medical Information and Education under the jurisdiction of the Secretary shall promote in an ethical manner the educational usefulness of the Society to the fellows, to all licensed physicians in Massachusetts and to the public. He shall also assist the officers, the Council and such district societies or committees as may request his services.

##### *Expenses of Officers, Executive Secretary,*

##### *Director of Medical Information and Education, and Committees*

**Section 9.** The traveling and incidental expenses of the officers of the Executive Secretary, of the Director of Medical Information and Education, of the committees of the Society elected by districts and of standing committees of the Society on request, shall be paid by the Treasurer on presentation of an itemized bill duly approved by the President.

#### APPENDIX NO. 8

December 12, 1947

Hamphrey L. McCarthy, M.D.  
Chairman, Massachusetts Medical Society  
479 Beacon Street  
Boston, Massachusetts

Dear Dr. McCarthy:

The following is a report of fee basis operations during the year 1947.

A new treatment procedure and form was evolved, after many months of discussion between Boston Regional Office Veterans Administration officials and officials of the Mass

sachusetts Medical Society. The prime object was to devise some system that would simplify the many exacting requirements of Government paper work detail and reduce bookkeeping for private doctors to a bare minimum.

The resultant procedure was inaugurated on July 1, 1947, and aside from several minor operational problems, did not present any unusual difficulty.

At the time of installation of the procedure, the Veterans Administration had a processing backlog of doctors' bills for medical treatment, amounting to almost seven months' work. Since the introduction of the new procedure this backlog has been virtually eliminated. At the present time the Boston Regional Office is within thirty days of being current on the payment of most bills for medical treatment.

Two major difficulties were experienced by the Veterans Administration in paying for medical treatment under the new system, the first being that a large percentage of doctors did not submit their bills within fifteen days from the end of the month in which treatment was rendered. It should be noted that bills submitted on or before that date will be paid promptly. Bills received after that date may be delayed as long as two or three months in payment. It therefore behooves every doctor to forward these forms without delay.

The second major difficulty is the incorrect preparation of the statement of services rendered.

The following are a few of the errors for which it was necessary to return the bills for correction:

1. Signature and registration number missing from lower right hand corner of Report of Treatment.
2. Signature and address missing from Statement of Services Rendered.
3. Report of Treatment is incomplete.
4. Dates and fees shown on Statement of Services Rendered does not register through cards onto pink copies. If pen is used, the entries should be made on both copies. If indelible pencil is used, entries will register through carbon satisfactorily.
5. Entries must be made in ink, by typewriter or indelible pencil. Ordinary pencil writing cannot be accepted.
6. Doctor's address is missing.
7. Statement of Services Rendered is incomplete.
8. Totals not shown on Statement of Services Rendered.
9. Fee charged on Statement of Services is in excess of fee authorized.
10. The number of visits charged on the statement is in excess of the number of visits authorized.
11. Treatments shown on Report of Treatment is not the disability for which authorization is granted.

During the month of July it was necessary to return for correction approximately 50 per cent of the bills rendered. This percentage has steadily declined until a level of approximately 7 per cent has been maintained for two months.

As a result of the many suggestions received from officials of the Massachusetts Medical Society and physician members, the Treatment Authorization Form was revised slightly

on the first of December and will also be used to authorize examinations for compensation purposes.

On the first of December also the list of general medical physicians, which formerly accompanied the authorization, was eliminated. Instead a letter is attached, instructing the veteran to report to any physician who has been approved for the care and treatment of veterans by the Massachusetts Medical Society and the Veterans Administration.

Veterans requiring specialistic treatment will be furnished with a list of qualified specialists.

At the present time there is a backlog in the payment of bills for examinations, amounting to about three months' work. It is anticipated that by the use of Form 10-900 this backlog will be eliminated in the near future.

During 1947, 28,228 examinations were made by fee-basis physicians at a total cost of \$227,793. During the same period 117,788 treatments were given at a cost of \$447,234.

The percentage break-down by types of examination and treatment is shown below:

TYPE	EXAMINATION TREATMENT	
	%	%
Ear, nose and throat	3	3
Eye	1	1
Genitourinary and gynecologic	2	1½
Heart	1½	1
Neurologic	1½	1½
Orthopedic	5	3
Physical therapy	—	8½
Psychiatric	8	5
Dermatology	1½	5½
Tuberculosis	—	1½
Venereal	—	—
General surgical	1½	1½
General physical	9½	60
X-ray and electrocardiographic	52½	1½
Laboratory	14	—
All other	2	3½

On the first of November a new fee schedule became effective as a result of an agreement between the Massachusetts Medical Society and the Veterans Administration. Certain fees may not be entirely adequate, however, the Medical Society is presently negotiating for increases where indicated.

A board of review has been established by the Massachusetts Medical Society to which private physicians and the Veterans Administration may present their problems regarding veterans' care and which already has handled and adjudicated many cases satisfactorily.

On the whole the year has been marked by better relations between private physicians and the Veterans Administration. Most physicians have been very patient and understanding, regarding the problems confronting the Veterans Administration during a year of tremendous expansion, and their practical suggestions, freely given, have contributed to a great extent to the evolution of a sounder and more efficient veterans' care program.

Officials of the Massachusetts Medical Society deserve much credit for many hours of devoted work, in solving problems of policy and procedure and in liaison with the Veterans Administration.

STEPHEN J. DALTON, M.D., Chief Medical Officer

Regional Office  
Veterans Administration

## CASE 34151

### PRESENTATION OF CASE

A fifty-nine-year-old woman entered the hospital because of hemoptysis.

Two months before admission she had an attack of "grippe," and one week later coughed up a large clot of blood. One month before admission she coughed up another blood clot and had occasional streaks of blood in the sputum. She lost 5 pounds in the two months prior to entry.

Four years before entry a left nephrectomy had been performed at another hospital, and a hypernephroma removed, following which she received twenty courses of x-ray treatments to the left nephrectomy scar. One and a half years later she entered this hospital with a soft mass in the left lumbar region extending from the iliac crest. X-ray examination at that time revealed a defect, 4 by 6 cm., in the crest of the ilium. The upper fourth of the left ilium was resected. Pathological examination revealed metastatic renal-cell carcinoma. Two years before entry diabetes was discovered, and she had taken 35 units of protamine-zinc insulin daily, augmented by 5 to 6 units of regular insulin.

Physical examination revealed a well developed and well nourished woman. A Grade III apical and aortic systolic murmur, which had been recorded on the previous admission, was heard. Diminished breath sounds and increased tactile fremitus were found over the left lower lobe. There was a large incisional hernia in the scar in the left flank.

The temperature was 99°F, the pulse 78, and the respirations 18. The blood pressure was 135 systolic, 65 diastolic.

Examination of the blood disclosed a hemoglobin of 10.3 gm and a white-cell count of 7500, with 56 per cent neutrophils, 30 per cent lymphocytes, 4 per cent eosinophils and 1 per cent basophils. Urinalysis showed a specific gravity of 1.012 and was negative for albumin, sugar and diacetic acid. The fasting blood sugar was 236 mg., the total protein 7.4 gm., and the nonprotein nitrogen 24 mg. per 100 cc. The prothrombin time was 21 seconds

(control, 16 seconds). A blood Hinton test was negative. A sputum smear was negative for tumor cells.

X-ray films of the chest showed an elevated diaphragm on the left side, with a hazy density involving most of the left side of the chest (Fig. 1). On the lateral view there was a band of increased density 3 cm. in diameter along the anterior portion of the chest wall, suggesting partial collapse of the left upper lobe. The right lung field was clear.

FIGURE 1

except for some areas of atelectasis just above the diaphragm. The heart was not unusual.

On the third hospital day a bronchoscopy was performed.

### DIFFERENTIAL DIAGNOSIS

DR. ALLEN G. BRAILEY: This patient had several things the matter with her, any one of which might have caused death under suitable circumstances. In fact we are very generously provided with three diagnoses concerning which there seems little ground for argument: she had diabetes mellitus, she probably had aortic stenosis, whether rheumatic or not is not clear, and she had renal-cell carcinoma. But she also had something else, the nature of which is not nearly so obvious—something that involved the lung or bronchus and was signalized by gross hemoptysis and by various abnormal physical and x-ray signs.

MAY we see the x-ray films?

DR. STANLEY M. WYMAN: This film which was taken three years before the present admission, shows the heart to have a prominent left ventricle, consistent with hypertension or aortic stenosis. The

lung fields are clear. This is a film of the lesion of the left iliac bone described, taken at the same time as that of the chest. This is the postoperative film taken later. The two films describing the lesion in the chest show the left leaf of the diaphragm to be elevated. There is a poorly defined area of hazy density overlying the upper two thirds of the left lung field medially, leaving a clear peripheral zone. The heart shadow shows a prominent left ventricle, but is otherwise not remarkable. The right lung field is clear. There is atelectasis at the base. The zone of density described in the anterior portion

FIGURE 2

of the chest in the lateral view is seen as a band of indefinite character. In this view it is quite consistent with partial collapse of the left upper lobe.

DR BRAILEY: Can you see the bronchus to the left upper lobe?

DR WYMAN: No, not adequately. There are no bony defects and no evidence of masses in the mediastinum or hili.

DR BRAILEY: The significant features of the chest lesion appear to be that it produced collapse of the left upper lobe and resulted in hemoptysis. It does not seem likely that any very extended differential diagnosis will be necessary, for there are not many conditions that will produce these changes. In fact, I think that only tuberculosis and neoplasm deserve serious consideration. Endobronchial tuberculosis leads inevitably, in time, to bronchial stenosis. It can also ulcerate and result in hemoptysis, but very rarely massive hemoptysis. But how massive was the hemoptysis? The record states that the patient coughed up "a large clot" of blood. But a large clot is more suggestive of a long period of

gentle oozing than the sudden rupture of a sizable vessel. I am therefore not sure that the bleeding was ever more than very moderate. On the other hand, I do not believe we can exclude the possibility of a small parenchymal cavitation near the hilus or behind the heart, which might have provided any degree of bleeding. It should be noted in passing that she was diabetic and that diabetic patients are especially prone to tuberculosis. A single sputum specimen is said to have shown no tumor cells. We are not told whether tubercle bacilli were looked for in the sputum or gastric contents. I am sure that a search of the sputum at least was made, and we must conclude therefore that no bacilli were found. Is it proper to ask how much of a search for tuberculosis was made?

DR TRACY B. MALLORY: Judging from the record, I should say that the search was not extensive.

DR BRAILEY: Let us leave tuberculosis for the moment and consider neoplasm. An adenoma of the bronchus might easily produce these symptoms and signs. It is a lesion that is prone to bleed and may bleed very briskly. It, of course, readily occludes the bronchus. In fact, the sequelae of such occlusion often bring the patient to the doctor. To be sure, adenoma is likely to appear at an earlier age, but no age is exempt. If we regard this history as indicative of a good deal of bleeding, then we have an argument in favor of adenoma as opposed to cancer, for bronchiogenic cancer, at least, is apt to result in blood streaking but not massive hemoptysis. The state of relative good health is perhaps a straw in favor of a benign lesion. Incidentally, one wonders if the "grippe" that is said to have ushered in the present illness was a transient pyogenic infection of the collapsed lobe.

Did the patient have bronchiogenic cancer? I think so, but it is a little unusual for a woman in previously good health to present gross hemoptysis as the first sign of cancer of the bronchus. However, bronchiogenic cancer remains a very definite possibility. There is the difficulty that if we agree that she had bronchiogenic cancer we give her not three, but four, potentially fatal diseases, and two of them are unrelated carcinomas. Multiple primary malignant tumors are not very rare. Drooker<sup>1</sup> has reported the history of a man who was successfully operated upon in this hospital for three separate unrelated cancers. Warren<sup>2</sup> reported in 1944 that in 3907 autopsies on patients with cancer, 6 per cent had two or more unrelated cancers. He and his colleagues estimated that the chance of developing cancer *de novo* is about eleven times greater in the person who already has a malignant tumor.

Finally, we must explore the possibility that the chest lesion was a metastasis of the renal-cell carcinoma. I see no reason why tumor cells might not lodge in the bronchial wall or so close to the bronchus as to erode or grow into the bronchus, with occlusion of the tube and subsequent ulceration.

tion and bleeding. The very fact that this case is presented for discussion makes me wonder if that is not precisely what took place, but such a pretty series of events must be excessively rare and to make such a diagnosis would require an unreasonable love for long shots.

I do not know how to decide between these various possibilities. Clinically, no such decision should have been made. The decision should merely have been to bronchoscope, but since I am expected to make a guess, I think it better judgment to guess that the patient had an adenoma of the bronchus.

DR ERNEST M. DALAND: I saw this woman on the first entry, when she had a metastatic lesion in the ilium and, at that time, no other metastases. We removed the crest of the ilium. There was quite a sizable tumor growing out through it. She did very well so far as that was concerned, at the time, except that she developed a large hernia in the scar. I subsequently followed her, and she came to me when she had the hemoptysis.

#### CLINICAL DIAGNOSIS

Primary bronchogenic carcinoma

DR BRAILEY'S DIAGNOSES

Renal-cell carcinoma  
Diabetes mellitus  
Rheumatic heart disease  
Adenoma of bronchus

#### ANATOMICAL DIAGNOSIS

Endobronchial metastasis of renal cell adenocarcinoma

#### PATHOLOGICAL DISCUSSION

DR EDWARD B. BENEDICT: Bronchoscopy showed a slightly irregular mass completely obstructing the left upper lobe bronchus. A portion of it looked vascular, — that is, it was a dark, hemorrhagic color, — and I hesitated to take a biopsy for fear of serious hemorrhage. But I did take hold of it with the forceps, and instead of my obtaining a biopsy specimen, the whole tumor mass came out. It was the size of the end of a finger. There was no bleeding. After removing it, I looked in through the bronchoscope, using the right-angle telescope, and could see all the terminal orifices of the upper lobe, and there was no sign of tumor in the bronchus.

DR MALLORY: The tumor that Dr. Benedict so successfully removed showed an adenocarcinoma of clear, vacuolated cells, characteristic of renal-cell adenocarcinoma, and without doubt a metastasis from the original hypernephroma. I believe that the patient has been bronchoscoped once again.

DR BENEDICT: About a month after the original bronchoscopy we looked in again and there was no sign of anything in the bronchus.

DR MALLORY: There was considerable debate regarding whether or not this patient should have further surgery.

DR BENEDICT: Dr. Daland and I talked that over. Since she has had two metastases she must have disease elsewhere, and we did not want to put her through another operation with the diabetes and so on. She also has developed an abdominal mass, which Dr. Wyman will demonstrate.

DR WYMAN: These two films show very nice aeration of the left upper lobe with a small amount of fluid in the costophrenic sinus (Fig. 2). Now there is a huge mass in the left midportion of the abdomen, which in one film seems to lie far posterior and displaces the stomach. It is consistent with a large recurrent tumor mass in the region of the left kidney.

#### CASE 34152

##### PRESENTATION OF CASE

**First admission.** A fifty-nine-year-old business executive entered the hospital complaining of chest pain.

A year and a half before admission the patient, who had been otherwise asymptomatic, developed mild anginal pain, followed in a few weeks by severe pain diagnosed as coronary thrombosis. Serial electrocardiograms were said to have shown a posterior myocardial infarct and then gradually to have returned to normal, the patient returned to his work and moderate activity. Seven weeks before admission he developed a bad cold, with a dry cough and slight fever, but no chest pain, he continued to cough and felt vaguely not well. Examination revealed no sign of disease. He did note, however, midepigastria distress, and one week later discomfort in the right side of the chest, extending from the xiphoid process to the right midaxillary line. This discomfort was described as dull in character but did prevent sleep, it was improved by lying on the left side and aggravated only slightly on deep breathing. There was no hemoptysis, dyspnea or orthopnea. Two weeks later he was noted to have a friction rub in the right lower portion of the chest and therefore was put to bed. The pain became worse and spread to the left side of the chest.

Physical examination was remarkable only in showing localized tenderness over both lung bases posteriorly, with fine moist rales. The legs were normal. There was no evidence of thrombosis. A chest film showed numerous areas of increased density in both lower-lung fields, lying close to the

pleural surfaces and varying in shape from round to linear. There was a small amount of fluid in both pleural cavities. The patient was treated for ten days with a course of dicumarol and discharged after improvement of the pain on 200 mg of dicumarol every three days. Despite this fairly large dosage of dicumarol the prothrombin time never went above 25 seconds.

*Final admission* (two weeks later) The patient was readmitted because of persistence of the dull aching pain in the right side of the chest. The pain was aggravated by breathing and lying down but still with little cough and no hemoptysis. An additional history, first elicited at this time, revealed intermittent episodes of epigastric distress and "indigestion" for three months, occurring between meals and at night but unrelated to food intake.

Physical examination showed a man who appeared ill, had lost weight and was in considerable discomfort, with pain in the right side of the chest and indigestion. There was a firm, nontender, round lymph node, 1.5 cm in diameter, in the left inguinal area. Both lung bases were dull, with moist rales and diminished breath sounds. The liver edge was palpable 2 cm below the costal margin, but not tender, the left lobe was palpable and questionably irregular.

Urinalysis showed only a + test for albumin and rare granular and hyaline casts in the sediment. The prothrombin time was 21 seconds (control, 16 seconds). The white-cell count was 8300. The photohemoglobin was 14.6 gm per 100 cc.

X-ray films of the chest disclosed no change. Barium given by mouth showed no abnormality in the stomach or duodenum. The cephalin-flocculation test was normal. The total protein was 6.9 gm per 100 cc. A determination of the acid phosphatase was 1.7 units per 100 cc, the phosphorus 3.8 mg, and the alkaline phosphatase 19.2 units per 100 cc.

The patient failed fairly rapidly. He continued to have pain in the right side of the chest and back and died three weeks later.

#### DIFFERENTIAL DIAGNOSIS

DR MERRILL SOSMAN\* This patient gave a characteristic clinical history of pulmonary infarcts. The x-ray films suggest pulmonary infarcts. He was treated for pulmonary infarction, so that it is obvious that there must be a trap here some place. The things that are missing are hemoptysis and an acute sudden episode, such as that generally occurring with pulmonary infarction. There was no tenderness in the calves, that fact was stressed. The pain in the right side of the chest continued, and the patient died three weeks after the second admission. I do not know whether or not a biopsy of a lymph node was done.

What else could have produced this history and x-ray findings, which so strongly suggest pulmonary

infarction? The first thing to think of is tumor emboli or tumor infarcts from some concealed source. The source is usually the abdomen and often retroperitoneal. We must therefore think about malignant lymphoma as a possible source of these pulmonary manifestations. There was no anemia to go with a primary lesion of the gastrointestinal tract, and the gastrointestinal examination was apparently negative, although there was one small questionable area. What else could have produced such a case? A pancreatic tumor will give a history and findings of this type. Carcinoma of the pancreas, occasionally renal carcinoma and occasionally rare tumors of the genital ridge, very rapidly growing and malignant, kill a man this quickly, with metastases that appear like infarcts in the lung.

The second group of possible causes to be considered are the rare infections. The infection, such as is presumed to produce periarteritis nodosa, is really an allergic phenomenon, I think. This patient had a cold and then got worse. I am rather inclined to lean on the syndrome of periarteritis nodosa as being more logical than metastatic tumor. The monograph written by Armstrong, Bailey and Sosman, but never published, states that periarteritis nodosa is a febrile disease, and this man had a little fever. The local presenting symptomatology depends entirely on the localization of the arterial involvement. Any organ or system may be involved. The ones involved most commonly are the kidneys, — 75 per cent of all patients with periarteritis nodosa had definite renal involvement, — and when that occurs the outlook is unfavorable. This patient had albumin and casts but no blood in the urine. I would have expected to see red cells or hematuria. The heart is involved in 60 per cent of cases. I do not know whether or not this patient had definite coronary-artery disease a year and a half previously. Clinically, the evidence of heart involvement is much less frequent, very often it is a surprising finding at autopsy. The gastrointestinal tract is involved in one third of the cases, producing the most widespread and variable symptomatology of all. The symptoms may be very mild, consisting of a discomfort such as this man had, or they may be very acute and simulate an acute surgical condition of the abdomen. In fact, some patients operated on for acute perforation or strangulation have been found to have periarteritis nodosa in a segment of the bowel. The liver is involved in periarteritis nodosa — I cannot find the exact percentage of cases. We notice that the phosphatase in the case under discussion was 19.2 units per 100 cc. With nothing demonstrable in any of the bones it makes me think that the elevated phosphatase was due to marked liver involvement. The lungs are involved in periarteritis nodosa much more commonly than one might think, the condition may simulate a

\*Radiologist Peter Bent Brigham Hospital, Boston

miliary tuberculosis and, at times, unresolved pneumonia or infarct. There probably are actual infarcts in some areas of the lung. That would fit in here very well. The eosinophilia that is stressed so often in reports of periarteritis nodosa apparently occurs only if the patient had preceding asthma. That limits the group to the 10 per cent of patients who do get eosinophilia. However, it does not rule it out. We have no differential blood smear. I assume that it was normal. There was no eosinophilia but no history of asthma, so that we would not expect it. There was no obvious inflammation or tenderness or muscle pain in the extremities. The subcutaneous tender nodules, which on biopsy are apt to give a characteristic lesion, are missing here. The leukocytosis that usually occurs in periarteritis nodosa is missing. The globulin is very often increased. The total protein may not be increased, but there may be an inversion of the albumin-globulin ratio, which is not mentioned in the record — the determination probably was not done.

There is no history of any previous injection of serum or any administration of sulfonamides. It would be interesting to know whether sulfonamides were given during the first chronic attack or the febrile attack. Sensitivity to any agent apparently precipitates the full blown disease.

Going over the x-ray films several times, we see a rather steadily progressive involvement of the bases of both lungs. Those who have seen the films or are close enough can find little triangular nodules well out in the periphery of the lung, mostly in the bases. Fluid developed on the right side and, toward the end, on the left side. All the films show one dense area, which is probably in the anteromedial section of the right lower lobe, possibly in the inferior section of the middle lobe, which looks like atelectasis. That raises the question of primary bronchiogenic carcinoma with rapid spread. The history is so short and the downhill course so rapid that it does not fit a case of primary carcinoma of the lung, which must be considered, however.

The gastrointestinal films are said to have been normal. The man who does the fluoroscopy has a great advantage over anyone looking at the films. He can detect individual lesions and get detailed spot films. The fact that they were not taken means to me that he did not see anything suspicious. There is an area about the middle third of the lesser curvature that looks irregular on the film six hours after the administration of barium, a calcified area or a small barium residue high up on the left flank. That may be of significance and may indicate a "carcinoma occulta" of the stomach, often very small, no bigger than the thumbnail. It may metastasize widely through the lungs and liver, but one may be unable to pick up the original lesion

in the x-ray film. In fact Dr Wolbach admits that he has difficulty at times in finding the primary tumor in the stomach.

To sum up the evidence, the three possibilities that occur to me are a rapidly growing malignant tumor, probably in the abdomen and most apt to be retroperitoneal, such as, pancreas, kidney, or retroperitoneal lymphoma, bronchiogenic carcinoma, possibly primary in the right lower lobe, and the very remote possibility of carcinoma occulta of the lesser curvature of the stomach. The other possibility is the one I have taken more time on — that is periarteritis nodosa. I have looked up the alkaline phosphatase in Greenstein's *Biochemistry of Cancer* and find that the alkaline phosphatase is given in nearly all conditions except periarteritis nodosa. I was not able to find out whether periarteritis nodosa raises the phosphatase. However we can rule out bone diseases from the x-ray film and blame the increased alkaline phosphatase on marked liver damage.

DR TRACY B. MALLORY: Are there any other comments or any alternative diagnoses?

DR SOSMAN: I would like to have some of these men help lead me on to the correct track. Dr Bauer, what have you got to say?

DR WALTER BAUER: I am surprised that you gave such a long dissertation on periarteritis nodosa in this case. I am much more inclined to believe that the patient had a retroperitoneal neoplasm, with metastases, or even carcinoma of the stomach seems to be a more likely possibility.

DR SOSMAN: Would it kill the patient that quickly? I would expect a more prolonged course.

DR BAUER: He had had myocardial infarction. Nothing is said about the manner of death.

DR MALLORY: There was no evidence of congestive failure.

DR BAUER: We certainly see eosinophilia in periarteritis nodosa in the absence of asthma. In our series about one third of the patients have eosinophilia, and that varies from time to time, being present on one occasion and absent on another. I never thought of the eosinophilia of periarteritis nodosa as occurring in people with asthma as a manifestation of disease. Certainly, that has not been borne out in our experience.

DR SOSMAN: You see a great many asthmatic patients here. Dr Rackemann has a large clinic.

DR MALLORY: Dr Robbins, do you agree with Dr Sosman?

DR LAURENCE L. ROBBINS: Dr Sosman has covered the things that we considered in our differential diagnosis, and I have to admit that early in the x-ray examination we were quite content that these were multiple pulmonary infarcts in the healing stage. The first film was taken approximately seven weeks after the original acute episode, and we thought they were consistent.

## CLINICAL DIAGNOSIS

## Carcinomatosis

## DR SOSMAN'S DIAGNOSIS

Periarteritis nodosa?

Pulmonary metastases (tumor emboli) from retroperitoneal tumor?

## ANATOMICAL DIAGNOSES

*Carcinoma of tail of pancreas, with invasion of spleen, left adrenal gland and posterior wall of stomach and metastases to liver and lungs*

Coronary sclerosis, with occlusion

Infarct of heart, old

Hydrothorax, bilateral

## PATHOLOGICAL DISCUSSION

DR MALLORY Shortly before death a lymph node from the groin was removed for biopsy and found to contain metastatic carcinoma, too undifferentiated to permit any guess regarding the primary site of the tumor. At autopsy many metastatic foci were found in the lungs and liver but no infarcts of the lung. There was a small ulcer on the posterior wall of the stomach. Behind this, in the tail of the pancreas, was a mass of tumor, which had directly invaded the spleen, the lower surface of the diaphragm and the left adrenal gland. It was our impression that the tumor was primary in the pancreas, with secondary involvement of the stomach rather than vice versa. We found no metastases to the skeleton. The autopsy also showed the scar of the old infarct of the heart in the posterior part of the interventricular septum,

and occlusion of the descending branch of the left coronary artery.

DR ALFRED KRANES How extensive were the metastases to the liver?

DR MALLORY They were numerous but small, replacing perhaps a third of the liver substance.

DR KRANES It hardly seems enough to warrant such a rise in phosphatase.

DR MALLORY No, jaundice never developed.

DR ROBBINS Was it your impression that the pulmonary metastases were arterial emboli?

DR MALLORY I think they probably were.

DR SOSMAN You would explain the shadows in the lung as vascular metastases?

DR MALLORY All metastatic nodules.

DR SOSMAN One thing I called attention to was the area in the left upper quadrant in the region of the tail of the pancreas, unfortunately about the same region as the irregularity in the stomach. I said that it looked more like calcification than residue of barium. Carcinoma of the pancreas not infrequently contains areas of calcification. I found that out the hard way. One of my students saw some calcified areas in the liver and I asked him what they were. He said, "metastases." I said, "You can throw that out because metastases never calcify, with the exception of primary osteogenic sarcoma of bone." The patient was later explored and found to have carcinoma of the pancreas with calcification in the original tumor and also calcification in the liver metastases, so that my absolute "no" was wrong again. It is quite possible that this shadow represented calcification in a primary tumor of the pancreas.

DR MALLORY I cannot answer that because we did not look for it.

## THE NATIONAL HEALTH PROGRAM

THE hearings before the Senate Subcommittee on Health on the Taft Bill (S-545) and the Wagner-Murray-Dingell Bill (S-2143), which began on May 21, 1947, will probably terminate shortly. In the three volumes of evidence already published and available there is much valuable information and some misinformation.

Out of the confusing and conflicting testimony grows a belief that there will not be any report favoring a compulsory program for sickness insurance from this committee or this Congress. It is also improbable that the Taft Bill as such will be reported out of committee. Legislation involving

huge expenditures would have to present convincingly good remedies for a demonstrably bad situation to get favorable consideration at this time.

It appears that as more people know more of the fundamentals, there is less support for the Social Security Board's plan. Chairman Smith circularized the governors of all the states and found that none favored the Wagner-Murray-Dingell Bill, whereas twenty-five favored the Taft Bill in principle. Even Governor Warren of California, who fought hard for a plan in his own state, is opposed to the Wagner-Murray-Dingell Bill and to socialized medicine.

In time evolutionary steps will probably be taken providing federal grants-in-aid to states where there is recognized inability to meet existing needs. The Government has so pre-empted tax sources that some states not in the needy group find federal subsidy acceptable.

The bill recently filed by Senator Saltonstall providing grants for local health units and another for school health services (S-1290) need clarification of purpose on such items as treatment. Steps leading toward the inclusion of a medical-care program in any legislation should be taken with extreme caution. At the hearing on this bill Dr. Martha Eliot, associate chief of the Children's Bureau, advocated thorough medical examination of school children every three or four years in preference to superficial annual inspections. Authorities on school health programs have been trying to persuade the Massachusetts legislature to adopt this point of view.

When tax dollars are sent to Washington for grants-in-aid programs it must be realized that states like Massachusetts are paying more than they receive in return. So far as the difference goes to needy states, we should not complain, but we should be realistic in weighing values received on federal programs. The Government has nothing to give that it has not first taken away.

The new Social Security administrator, Oscar Ewing, is calling a group to a conference early in May to formulate a ten years' program for health. This can be a valuable event for the nation, but it must be remembered that the board may have pre-packaged programs that need critical study, however well conceived they seem.

## GREATER BOSTON COMMUNITY SURVEY

OPERATING costs of social and health agencies in the Boston area, paralleling the cost of living in general, have scaled new heights. Deficits are accumulating, and the Greater Boston Community Fund, the Dutch uncle of them all, is feeling the pinch. Established in 1935 to raise funds for 115 agencies in municipal Boston, this super-agency must now provide the sinews of peace for 339 agencies serving fifty-five contiguous communities.

The writing on the wall has become more apparent. As a result of the present disturbing condition the governing boards of the Greater Boston Community Fund and the Greater Boston Community Council early last year invited Robert Cutler, president of the Old Colony Trust Company, to head a committee of citizens to direct a Greater Boston Community Survey of Social and Health Needs and Services.

Mr. Cutler, with no apparent difficulty, persuaded one hundred and eighty out of a panel of one hundred and eighty-four leading citizens to serve on such a committee. In March, 1947, an executive committee of sixteen members was appointed. The field to be covered in the survey has been divided into five divisions, comprising public health, hospitals, recreation and group work, voluntary case-work and statistics and public welfare. The director of the survey is Robert P. Lane, for twelve years executive director of the Welfare Council of New York City. The section on public health is under the direction of Ira V. Hiscock, Sc.D., chairman of the Department of Public Health of Yale University, assisted by Dr. Hugh R. Leavell, professor of public-health practice of the Harvard University School of Public Health, and an advisory group, that on hospitals is under the guidance of Dr. Basil C. MacLean, director of Strong Memorial Hospital, Rochester, New York, and Dr. Albert W. Snoke, director of Grace-New Haven Community Hospital, New Haven, Connecticut.

A preliminary study of the Survey reveals that \$88,000,000 was spent in 1946 by the tax-supported and voluntary agencies of Greater Boston, or \$44.65 per capita for the inhabitants of the area. The corresponding average in twenty-nine selected cities

of the country was \$32.48. In the health field \$21.12 was spent per capita in the Boston area as compared with \$14.86 for the same twenty-nine representative cities. In Greater Boston the recipients of these services paid 23.9 per cent of their costs, in the other areas 29.7 per cent.

A question naturally rises that must be answered. Do the greater costs in metropolitan Boston as compared with other areas indicate that a better job is being done here, or that it is being done less efficiently? The survey is expected to find the answer, but it is apparent that in any event economies must be practiced and still greater efficiency achieved if social welfare is to remain solvent.

---

 THE JOURNAL OF BONE AND JOINT SURGERY

*The Journal of Bone and Joint Surgery* has this year inaugurated a new plan of publication. Surgeons of the United States of America and the British Commonwealth of Nations are to share, in jointly publishing the *Journal*, the tasks of recording developments in orthopedic surgery.

The *Journal*, formerly a quarterly, now appears in eight issues, four numbers published in Britain alternate with four numbers published, as heretofore, in the United States. The British editorial board includes representatives from the Nations of the British Commonwealth, the American editorial board is composed of representatives of the different sections of the United States.

Through the new co-publication the scope of the *Journal* is extended, a fuller realization of international aim becomes possible. Greater opportunity is anticipated for readers to follow orthopedic developments in a single journal, not only in their own country but throughout the world.

In this larger journal there is increased space for the publication of significant articles, through separate issues national individuality is retained. Clinical and scientific contributions from other countries are welcome, as formerly, and may be found in all issues.

The present plan is the outgrowth of a policy established in 1919 and adhered to ever since, whereby the *Journal* has been the official organ of

the American and the British Orthopaedic associations. As surgery has advanced the *Journal* has grown. The importance of further expansion has become evident. In the spring of 1947 representatives of orthopedic surgery in the two lands met to continue the long association and, at the same time, more fully to meet the growing needs of expression of their branch of surgery. From their recommendations came the new plan of publication under which the *Journal* now appears.

This departure is unique in the history of medical journalism. That the task is a great one is recognized. The standard of publication sought is unusually high. Although *The Journal of Bone and Joint Surgery* is certainly representative of orthopedic development in the English-speaking countries, it is hoped and expected that it will increasingly typify progress in this broad division of surgery throughout the world.

## MASSACHUSETTS MEDICAL SOCIETY

### FEE-BASIS OPERATIONS DURING 1947

The following letter, embodying a report of the Boston Regional Office, Veterans Administration, on fee-basis operations during 1947, is presented for the information of the Society.

H. QUIMBY GALLUPE, *Secretary*

December 12 1947

Humphrey L. McCarthy, M.D., Chairman  
Veterans Administration Board of Review

Dear Dr. McCarthy:

The following is a report of Fee Basis Operations during the year 1947.

A new treatment procedure and form were evolved after many months of discussion between Boston Regional Office, Veterans Administration officials and officials of the Massachusetts Medical Society. The prime object was to devise some system which would simplify the many exacting requirements of government paper work detail and reduce bookkeeping for private doctors to a bare minimum.

The resultant procedure was inaugurated on July 1 1947 and aside from several minor operational problems did not present any unusual difficulty.

At the time of installation of the procedure the Veterans Administration had a processing backlog of doctors' bills for medical treatment amounting to almost seven months work. Since the introduction of the new procedure this backlog has been virtually eliminated. At the present time the Boston Regional Office is within thirty days of being current on the payment of most bills for medical treatment.

Two major difficulties were experienced by the Veterans Administration in paying for medical treatment under the new system, the first being that a large percentage of doctors did not submit their bills within fifteen days from the end of the month in which treatment was rendered. It should be noted that bills submitted on or before that date will be paid promptly. Bills received after

that date may be delayed as long as two or three months in payment. It therefore behooves every doctor to forward these forms without delay.

The second major difficulty is the incorrect preparation of the statement of services rendered.

The following are a few of the errors for which it was necessary to return the bills for correction:

- 1 Signature and registration number missing from lower right-hand corner of Report of Treatment
- 2 Signature and address missing from Statement of Services rendered
- 3 Report of Treatment is incomplete
- 4 Dates and fees shown on Statement of Services Rendered does not register through cards onto pink copies. If pen is used the entries should be made on both copies. If indelible pencil is used entries will register through carbon satisfactorily.
- 5 Entries must be made in ink by typewriter or indelible pencil. Ordinary pencil writing cannot be accepted.
- 6 Doctor's address is missing.
- 7 Statement of Services Rendered is incomplete.
- 8 Totals not shown on Statement of Services Rendered.
- 9 Fee charged on Statement of Services is in excess of fee authorized.
- 10 The number of visits charged on the Statement is in excess of the number of visits authorized.
- 11 Treatments shown on Report of Treatment is not the disability for which authorization is granted.

During the month of July it was necessary to return for correction approximately 50 per cent of the bills rendered. This percentage has steadily declined until a level of approximately 7 per cent has been maintained for two months.

As a result of the many suggestions received from officials of the Massachusetts Medical Society and Physician Members, the Treatment Authorization Form was revised slightly on the first of December and will also be used to authorize examinations for compensation purposes.

On the first of December also the list of general medical physicians which formerly accompanied the authorization was eliminated. Instead a letter is attached instructing the veteran to report to any physician who has been approved for the Care and Treatment of Veterans by the Massachusetts Medical Society and the Veterans Administration. Veterans requiring specialistic treatment will be furnished with a list of qualified specialists.

At the present time there is a backlog in the payment of bills for examinations amounting to about three months work. It is anticipated that by the use of Form 10-900s this backlog will be eliminated in the near future.

During 1947 28 228 examinations were made by fee basis physicians at a total cost of \$227 793. During the same period 117 788 treatments were given at a cost of \$447 254.

The percentage breakdown by types of examination and treatment is shown below:

	TYPE	EXAMINATION	TREATMENT
F N T		3%	1%
Pyc		1%	1%
U & Gyn		2%	1%
Heart		1%	1%
Neurological		1%	1%
Orthopedic		1%	1%
Physical Therapy		1%	1%
Psychiatric		1%	1%
Dermatology		1%	1%
T.R.		1%	1%
Neural		1%	1%
Gen. Surg.		1%	1%
Ne. Physiol.		1%	1%
X-Ray & EKG		1%	1%
Laboratory		1%	1%
All Other		1%	1%

On the first of November a new Fee Schedule became effective as a result of an agreement between the Massachusetts Medical Society and the Veterans Administration. Certain fees may not be entirely adequate however the Medical Society is presently negotiating for increases where indicated.

## GREATER BOSTON COMMUNITY SURVEY

OPERATING costs of social and health agencies in the Boston area, paralleling the cost of living in general, have scaled new heights. Deficits are accumulating, and the Greater Boston Community Fund, the Dutch uncle of them all, is feeling the pinch. Established in 1935 to raise funds for 115 agencies in municipal Boston, this super-agency must now provide the sinews of peace for 339 agencies serving fifty-five contiguous communities.

The writing on the wall has become more apparent. As a result of the present disturbing condition the governing boards of the Greater Boston Community Fund and the Greater Boston Community Council early last year invited Robert Cutler, president of the Old Colony Trust Company, to head a committee of citizens to direct a Greater Boston Community Survey of Social and Health Needs and Services.

Mr. Cutler, with no apparent difficulty, persuaded one hundred and eighty out of a panel of one hundred and eighty-four leading citizens to serve on such a committee. In March, 1947, an executive committee of sixteen members was appointed. The field to be covered in the survey has been divided into five divisions, comprising public health, hospitals, recreation and group work, voluntary case-work and statistics and public welfare. The director of the survey is Robert P. Lane, for twelve years executive director of the Welfare Council of New York City. The section on public health is under the direction of Ira V. Hiscock, Sc.D., chairman of the Department of Public Health of Yale University, assisted by Dr. Hugh R. Leavell, professor of public-health practice of the Harvard University School of Public Health, and an advisory group, that on hospitals is under the guidance of Dr. Basil C. MacLean, director of Strong Memorial Hospital, Rochester, New York, and Dr. Albert W. Snoke, director of Grace-New Haven Community Hospital, New Haven, Connecticut.

A preliminary study of the Survey reveals that \$88,000,000 was spent in 1946 by the tax-supported and voluntary agencies of Greater Boston, or \$44.65 per capita for the inhabitants of the area. The corresponding average in twenty-nine selected cities

of the country was \$32.48. In the health field \$21.12 was spent per capita in the Boston area as compared with \$14.86 for the same twenty-nine representative cities. In Greater Boston the recipients of these services paid 23.9 per cent of their costs, in the other areas 29.7 per cent.

A question naturally rises that must be answered. Do the greater costs in metropolitan Boston as compared with other areas indicate that a better job is being done here, or that it is being done less efficiently? The survey is expected to find the answer, but it is apparent that in any event economies must be practiced and still greater efficiency achieved if social welfare is to remain solvent.

## MASSACHUSETTS MEDICAL SOCIETY

### FEE-BASIS OPERATIONS DURING 1947

The following letter, embodying a report of the Boston Regional Office, Veterans Administration, on fee-basis operations during 1947 is presented for the information of the Society.

H. QUIMBY GALLUPE, *Secretary*

December 12 1947

Humphrey L. McCarthy, M.D., Chairman  
Veterans Administration Board of Review

Dear Dr. McCarthy:

The following is a report of Fee Basis Operations during the year 1947.

A new treatment procedure and form were evolved after many months of discussion between Boston Regional Office Veterans Administration officials and officials of the Massachusetts Medical Society. The prime object was to devise some system which would simplify the many exacting requirements of government paper work detail and reduce bookkeeping for private doctors to a bare minimum.

The resultant procedure was inaugurated on July 1 1947 and aside from several minor operational problems did not present any unusual difficulty.

At the time of installation of the procedure the Veterans Administration had a processing backlog of doctors' bills for medical treatment, amounting to almost seven months work. Since the introduction of the new procedure this backlog has been virtually eliminated. At the present time the Boston Regional Office is within thirty days of being current on the payment of most bills for medical treatment.

Two major difficulties were experienced by the Veterans Administration in paying for medical treatment under the new system the first being that a large percentage of doctors did not submit their bills within fifteen days from the end of the month in which treatment was rendered. It should be noted that bills submitted on or before that date will be paid promptly. Bills received after

that date may be delayed as long as two or three months to payment. It therefore behooves every doctor to forward these forms without delay.

The second major difficulty is the incorrect preparation of the statement of services rendered.

The following are a few of the errors for which it was necessary to return the bills for correction.

- 1 Signature and registration number missing from lower right-hand corner of Report of Treatment.
- 2 Signature and address missing from Statement of Services rendered.
- 3 Report of Treatment is incomplete.
- 4 Dates and fees shown on Statement of Services. Rendered does not register through cards onto pink copies. If pen is used the entries should be made on both copies. If indelible pencil is used, entries will register through carbon satisfactorily.
- 5 Entries must be made in ink, by typewriter or in indelible pencil. Ordinary pencil writing cannot be accepted.
- 6 Doctor's address is missing.
- 7 Statement of Services Rendered is incomplete.
- 8 Totals not shown on Statement of Services Rendered.
- 9 Fee charged on Statement of Services is in excess of fee authorized.
- 10 The number of visits charged on the Statement is in excess of the number of visits authorized.
- 11 Treatments shown on Report of Treatment is not the disability for which authorization is granted.

During the month of July it was necessary to return for correction approximately 50 per cent of the bills rendered. This percentage has steadily declined until a level of approximately 7 per cent has been maintained for two months.

As a result of the many suggestions received from officials of the Massachusetts Medical Society and Physician Members the Treatment Authorization Form was revised slightly on the first of December and will also be used to authorize examinations for compensation purposes.

On the first of December also the list of general medical physicians which formerly accompanied the authorization was eliminated. Instead a letter is attached, instructing the veteran to report to any physician who has been approved for the Care and Treatment of Veterans by the Massachusetts Medical Society and the Veterans Administration. Veterans requiring specialist treatment will be furnished with a list of qualified specialists.

At the present time there is a backlog in the payment of bills for examinations, amounting to about three months work. It is anticipated that by the use of Form 10-9005 this backlog will be eliminated in the near future.

During 1947 28,228 examinations were made by Fee Basis Physicians at a total cost of \$227,793. During the same period 117,788 treatments were given at a cost of \$447,254.

The percentage breakdown by types of examination and treatment is shown below.

TYPE	EXAMINATION	TREATMENT
General	35%	31%
Internal Medicine	25%	16%
Neurological	13%	11 1/2%
Orthopedic	2%	1 1/2%
Physical Therapy	8 1/2%	8 1/2%
Psychiatric	1%	1 1/2%
Dermatology	1%	1 1/2%
T.B.	—	—
Urological	—	—
Gynecology	1 1/2%	1 1/2%
Gen. Physical	4 1/2%	4 1/2%
Neurological	52 1/2%	3 1/2%
Laboratory	14%	14%
All Other	2%	1 1/2%

On the first of November a new Fee Schedule became effective as a result of an agreement between the Massachusetts Medical Society and the Veterans Administration. Certain fees may not be entirely adequate however the Medical Society is presently negotiating for increases where indicated.

## GREATER BOSTON COMMUNITY SURVEY

OPERATING costs of social and health agencies in the Boston area, paralleling the cost of living in general, have scaled new heights. Deficits are accumulating, and the Greater Boston Community Fund, the Dutch uncle of them all, is feeling the pinch. Established in 1935 to raise funds for 115 agencies in municipal Boston, this super-agency must now provide the sinews of peace for 339 agencies serving fifty-five contiguous communities.

The writing on the wall has become more apparent. As a result of the present disturbing condition the governing boards of the Greater Boston Community Fund and the Greater Boston Community Council early last year invited Robert Cutler, president of the Old Colony Trust Company, to head a committee of citizens to direct a Greater Boston Community Survey of Social and Health Needs and Services.

Mr. Cutler, with no apparent difficulty, persuaded one hundred and eighty out of a panel of one hundred and eighty-four leading citizens to serve on such a committee. In March, 1947, an executive committee of sixteen members was appointed. The field to be covered in the survey has been divided into five divisions, comprising public health, hospitals, recreation and group work, voluntary case-work and statistics and public welfare. The director of the survey is Robert P. Lane, for twelve years executive director of the Welfare Council of New York City. The section on public health is under the direction of Ira V. Hiscock, Sc.D., chairman of the Department of Public Health of Yale University, assisted by Dr. Hugh R. Leavell, professor of public-health practice of the Harvard University School of Public Health, and an advisory group, that on hospitals is under the guidance of Dr. Basil C. MacLean, director of Strong Memorial Hospital, Rochester, New York, and Dr. Albert W. Snoke, director of Grace-New Haven Community Hospital, New Haven, Connecticut.

A preliminary study of the Survey reveals that \$88,000,000 was spent in 1946 by the tax-supported and voluntary agencies of Greater Boston, or \$44.65 per capita for the inhabitants of the area. The corresponding average in twenty-nine selected cities

of the country was \$32.48. In the health field \$21.17 was spent per capita in the Boston area as compared with \$14.86 for the same twenty-nine representative cities. In Greater Boston the recipients of these services paid 23.9 per cent of their costs, in the other areas 29.7 per cent.

A question naturally rises that must be answered. Do the greater costs in metropolitan Boston as compared with other areas indicate that a better job is being done here, or that it is being done less efficiently? The survey is expected to find the answer, but it is apparent that in any event economies must be practiced and still greater efficiency achieved if social welfare is to remain solvent.

---

### THE JOURNAL OF BONE AND JOINT SURGERY

*The Journal of Bone and Joint Surgery* has this year inaugurated a new plan of publication. Surgeons of the United States of America and the British Commonwealth of Nations are to share, in jointly publishing the *Journal*, the tasks of recording developments in orthopedic surgery.

The *Journal*, formerly a quarterly, now appears in eight issues, four numbers published in Britain alternate with four numbers published, as heretofore, in the United States. The British editorial board includes representatives from the Nations of the British Commonwealth, the American editorial board is composed of representatives of the different sections of the United States.

Through the new co-publication the scope of the *Journal* is extended, a fuller realization of international aim becomes possible. Greater opportunity is anticipated for readers to follow orthopedic developments in a single journal, not only in their own country but throughout the world.

In this larger journal there is increased space for the publication of significant articles, through separate issues national individuality is retained. Clinical and scientific contributions from other countries are welcome, as formerly, and may be found in all issues.

The present plan is the outgrowth of a policy established in 1919 and adhered to ever since, whereby the *Journal* has been the official organ of

the American and the British Orthopaedic associations. As surgery has advanced the *Journal* has grown. The importance of further expansion has become evident. In the spring of 1947 representatives of orthopedic surgery in the two lands met to continue the long association and, at the same time, more fully to meet the growing needs of expression of their branch of surgery. From their recommendations came the new plan of publication under which the *Journal* now appears.

This departure is unique in the history of medical journalism. That the task is a great one is recognized. The standard of publication sought is unusually high. Although *The Journal of Bone and Joint Surgery* is certainly representative of orthopedic development in the English-speaking countries, it is hoped and expected that it will increasingly typify progress in this broad division of surgery throughout the world.

## MASSACHUSETTS MEDICAL SOCIETY

### FEE-BASIS OPERATIONS DURING 1947

The following letter, embodying a report of the Boston Regional Office, Veterans Administration on fee-basis operations during 1947 is presented for the information of the Society.

H. QUIMBY GALLUPE, *Secretary*

December 12 1947

Humphrey L. McCarthy, M.D., Chairman  
Veterans Administration Board of Review

Dear Dr. McCarthy:

The following is a report of Fee Basis Operations during the year 1947.

A new treatment procedure and form were evolved after many months of discussion between Boston Regional Office Veterans Administration officials and officials of the Massachusetts Medical Society. The prime object was to devise some system which would simplify the many exacting requirements of government paper work detail and reduce bookkeeping for private doctors to a bare minimum.

The resultant procedure was inaugurated on July 1 1947 and aside from several minor operational problems did not present any unusual difficulty.

At the time of installation of the procedure, the Veterans Administration had a processing backlog of doctors' bills for medical treatment, amounting to almost seven months' work. Since the introduction of the new procedure this backlog has been virtually eliminated. At the present time the Boston Regional Office is within thirty days of being current, on the payment of most bills for medical treatment.

Two major difficulties were experienced by the Veterans Administration in paying for medical treatment under the new system: the first being that a large percentage of doctors did not submit their bills within fifteen days from the end of the month in which treatment was rendered. It should be noted that bills submitted on or before that date will be paid promptly. Bills received after

that date may be delayed as long as two or three months in payment. It therefore behooves every doctor to forward these forms without delay.

The second major difficulty is the incorrect preparation of the statement of services rendered.

The following are a few of the errors for which it was necessary to return the bills for correction:

- 1 Signature and registration number missing from lower right hand corner of Report of Treatment
- 2 Signature and address missing from Statement of Services rendered
- 3 Report of Treatment is incomplete
- 4 Dates and fees shown on Statement of Services Rendered does not register through cards onto pink copies. If pen is used the entries should be made on both copies. If indelible pencil is used entries will register through carbon satisfactorily.
- 5 Entries must be made in ink by typewriter or in indelible pencil. Ordinary pencil writing cannot be accepted.
- 6 Doctor's address is missing
- 7 Statement of Services Rendered is incomplete
- 8 Totals not shown on Statement of Services Rendered
- 9 Fee charged on Statement of Services is in excess of fee authorized
- 10 The number of visits charged on the Statement is in excess of the number of visits authorized
- 11 Treatments shown on Report of Treatment is not the disability for which authorization is granted

During the month of July it was necessary to return for correction approximately 50 per cent of the bills rendered. This percentage has steadily declined until a level of approximately 7 per cent has been maintained for two months.

As a result of the many suggestions received from officials of the Massachusetts Medical Society and Physician Members the Treatment Authorization Form was revised slightly on the first of December and will also be used to authorize examinations for compensation purposes.

On the first of December also the list of general medical physicians which formerly accompanied the authorization was eliminated. Instead a letter is attached instructing the veteran to report to any physician who has been approved for the Care and Treatment of Veterans by the Massachusetts Medical Society and the Veterans Administration. Veterans requiring specialist treatment will be furnished with a list of qualified specialists.

At the present time there is a backlog in the payment of bills for examinations amounting to about three months' work. It is anticipated that by the use of Form 10-900 this backlog will be eliminated in the near future.

During 1947 28,228 examinations were made by Fee Basis Physicians at a total cost of \$227,793. During the same period 117,788 treatments were given at a cost of \$447,254.

The percentage breakdown by types of examination and treatment is shown below:

TYPE	EXAMINATION	TREATMENT
E. N. T.	3%	3%
Eye	1 1/2%	1 1/2%
O. T. & C. S.	1 1/2%	1 1/2%
Heart	1 1/2%	1 1/2%
Neurological	1 1/2%	1 1/2%
Orthopaedic	1 1/2%	1 1/2%
Physical Therapy	1 1/2%	1 1/2%
Psychiatric	1 1/2%	1 1/2%
Dermatologist	1 1/2%	1 1/2%
General	1 1/2%	1 1/2%
Gen. Phys. & Surg.	1 1/2%	1 1/2%
Gen. Phys. & Surg.	1 1/2%	1 1/2%
Lab. & EKG	1 1/2%	1 1/2%
Laboratory	1 1/2%	1 1/2%
All Other	1 1/2%	1 1/2%

On the first of November a new Fee Schedule became effective as a result of an agreement between the Massachusetts Medical Society and the Veterans Administration. Certain fees may not be entirely adequate, however. The Medical Society is presently negotiating for increases where indicated.

A Board of Review has been established by the Medical Society to which private physicians and the Veterans Administration may present their problems regarding veterans' care, and already have handled and adjudicated many cases satisfactorily.

On the whole the year has been marked by better relations between the private physicians and the Veterans Administration. Most physicians have been very patient and understanding, with regard to the problem confronting the Veterans Administration during a year of tremendous expansion and their practical suggestions, freely given have contributed to a great extent to the evolution of a sounder and more efficient Veterans' Care Program.

Officials of the Massachusetts Medical Society deserve much credit for many hours of devoted work, in solving problems of policy and procedure, and in liaison with the Veterans Administration.

STEPHEN J. DALTON, M.D., *Medical Director*

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*Textbook of the Ear, Nose and Throat* By Francis L. Lederer, M.D., professor and head, Department of Otolaryngology, University of Illinois College of Medicine, chief, Otolaryngological Service, Research and Educational Hospital, and director of education and chief of the Ear, Nose and Throat Service, Illinois Eye and Ear Infirmary, and Abraham R. Hollender, M.Sc., M.D., attending otolaryngologist, St. Francis Hospital, Miami Beach, Florida. Second edition. 8°, cloth, 596 pp., with 182 illustrations. Philadelphia: F. A. Davis Company, 1947. \$7.00.

This textbook, written primarily for students, first published in 1942, and reprinted in 1943 and 1944, has been revised to include recent advances in the subject, especially in the field of chemotherapy and antibiotics. The material is well organized, and the text well written and printed with a good, readable type. The illustrations are excellent. The volume is recommended for medical libraries.

*Illustrations of Regional Anatomy* By E. B. Jamieson, M.D. Seven sections. Seventh edition. 8°, paper, 320 plates. Baltimore: Williams and Wilkins Company, 1947. \$20.00.

This compendium of regional anatomy, first published in 1934, has been corrected in this seventh edition. The set has evidently filled a need in anatomic teaching, since all the editions have been exhausted comparatively soon after publication. The illustrations are in color and without text. The plates were printed in Great Britain and bound in the United States.

*Physical Medicine in General Practice* By William Bierman, M.D., attending physical therapist, Mount Sinai Hospital, and assistant clinical professor of medicine, Columbia University College of Physicians and Surgeons. With a chapter on medical rehabilitation by Dr. Sidney Licht. Second edition, revised and enlarged. 8°, cloth, 686 pp., with 310 illustrations. New York: Paul B. Hoeber, Incorporated, 1947. \$8.00.

Dr. Bierman, in this second edition of his treatise, first published in 1944, has revised the text to incorporate advances in knowledge in the field of physical medicine. Included in the new material are the combination of penicillin and fever therapy in the treatment of syphilis and early ambulation in various medical and surgical conditions. The first fifteen chapters deal with the various special means of therapy, including heat and cold and hydrotherapy, climatotherapy, sun, infrared and ultraviolet radiation, diathermy, fever therapy, massage, exercise and occupational therapy, and special chapters on medical rehabilitation and the conduct of treatments. The remaining chapters discuss the diseases

and conditions of the systems of the body, amenable to treatment by physical means. A list of selected references is appended to each chapter. An appendix is devoted to apparatus. A good index concludes the volume. The text is printed with a good type, on good paper.

*Conference on Metabolic Aspects of Convalescence. Transactions of the thirteenth meeting, Naushon Island, Woods Hole, Massachusetts, June 10, 11, 1946.* 8°, paper, 232 pp., with 67 illustrations and 26 tables. *Transactions of the fourteenth meeting, New York, November 12, 13, 1946.* 8°, paper, 190 pp., with 78 illustrations and 12 tables. New York: The Conference, 1947. Thirteenth meeting \$2.00 per copy. Fourteenth meeting \$2.25 per copy.

These two volumes of proceedings contain the papers read at the conferences held in 1946. The fourteenth meeting was featured by a symposium on bone metabolism. The other papers discussed various aspects of the subject. The thirteenth volume contains an index of contents of all the previous volumes and also a list of libraries where complete sets of the proceedings have been deposited. There are three sets in Boston — at the Boston Medical Library, the Harvard Medical School and the Massachusetts General Hospital. The volumes should be in all medical libraries.

*Diseases of the Nervous System* By W. Russell Brain, D.M. (Oxon), F.R.C.P. (London), physician to the London Hospital and to the Maida Vale Hospital for Nervous Diseases. Third edition. Oxford Medical Publications. 8°, cloth, 987 pp., with 79 illustrations. London: Oxford University Press, 1947. \$10.75.

This new edition of a standard work, first published in 1933, and last revised in 1942, has again been revised to include information gained during World War II. A chapter on nutritional disorders of the nervous system and sections on equine encephalitis, the nervous complications of epidemic hepatitis, myelopathy, spinal radiculitis and platybasia have been added. The section on aphasia has been rewritten, including material on disorders of the body image. Material has been added on chemotherapy, including the use of penicillin in meningitis and neurosyphilis, costoclavicular syndromes, herniated lumbar intervertebral disks, bronchial neuritis and the neurology of the lipodoses. The last section on the psychologic aspects of neurology includes two new sections on the status of psychogenic symptoms and psychotherapy and on psychometric tests. Lists of selected references are appended to each disease or section of the text. The type and printing are excellent, but the use of a heavy, filled paper makes the volume too heavy for its size. The book should be in all medical libraries.

*The Louse. An account of the lice which infest man, their medical importance and control.* By Patrick A. Buxton, C.M.G., F.R.S., director, department of medical entomology, London School of Hygiene and Tropical Medicine, and professor of medical entomology, University of London. Second edition. 8°, cloth, 164 pp., with 47 illustrations and 14 tables. Baltimore: Williams and Wilkins Company, 1946. \$3.25.

This British monograph, first published in 1941, has been revised to include the advances in knowledge of the subject since the publication of the first edition. The volume is well published and should be in all medical and public-health libraries.

*Practical Emulsions* By H. Bennett, technical director, Glyco Products Company, Inc., and editor, *Commercial Waxes, Chemical and Technical Dictionary, Chemical Formulary* and a so forth. Second, completely revised edition, including a symposium on *Emulsifying Agents and Emulsions in Industry*. 8°, cloth, 568 pp. Brooklyn, New York: Chemical Publishing Company, Incorporated, 1947. \$8.50.

This new edition of an authoritative technical treatise has been carefully revised and brought up to date. Material has been added on partial fatty-acid esters of polyhydric alcohols and their application to food products and also special sections on the use of soap, lecithin and pectin as emulsifying agents and surface-active germicides. A symposium on

industrial emulsions has been added including their use in leather synthetic latex polishes cosmetics, paints, dyeing and coloring. New formulas have been included in the appropriate section. In this section the chapters on cosmetics and drug emulsions food emulsions and medicinal emulsions are of medical interest. A good index concludes the text. The book is well printed with a good type but the use of heavy coated paper is to be deplored in a volume without illustrations. The book is recommended as a reference source on its subject.

*Therapeutics of Infancy and Childhood*. Edited by Harry R. Litchfield M.D., consultant in pediatrics Rockaway Beach Hospital Rockaway Beach New York attending pediatrician Beth El Hospital, Brooklyn Women's Hospital and Brooklyn Thoracic Hospital and chief in pediatrics East New York Dispensary Brooklyn and Leon H. Dembo M.D. visiting pediatrician St. Luke's and St. Ann's hospitals and consulting pediatrician Polyclinic Hospital, Cleveland Third edition. 5 volumes illustrated 8, cloth, desk index 148 pp. vol. 1 869 pp., vol. 2, 825 pp. vol. 3 750 pp. and vol. 4 829 pp. Philadelphia F. A. Davis Company 1947 \$40.00

This popular system first published in 1942 has been revised to bring the subject matter up to date since the publication of the previous edition in 1945. The work is the joint effort of one hundred and twenty six contributors specialists in their particular fields. The subject matter is classified by the systems of the body and by topics and is preceded by material of a general character. The chapter on chemotherapy has been largely rewritten and the sections on antibiotic treatment, including penicillin and streptomycin have been amplified. The material on cystic fibrosis of the pancreas celiac disease rheumatic fever Rh factor allergy and folic acid has been revised to date. The present-day treatment of virus pneumonia, toxoplasmosis and the dysenteries is presented in its practical aspects. A comprehensive index of a hundred and forty-eight pages constitutes a separate volume. The work is well published in every way. The type printing and paper are excellent. The volumes are comparatively light for their size. The production is a credit to the publisher. The work is recommended for all medical libraries and should prove valuable as a reference source for physicians with children as their patients.

## NOTICES

### ANNOUNCEMENT

Dr. Milton H. Rodofsky announces the opening of an office for the practice of psychiatry at 341 Beacon Street Boston

### GREATER BOSTON MEDICAL SOCIETY

A meeting of the Greater Boston Medical Society will be held in the auditorium of the Beth Israel Hospital on Tuesday April 20 at 8:15 p.m. A symposium entitled "The Acute Abdomen" will be presented.

The Acute Abdomen in Pediatric Practice Dr. Henry W. Hudson Jr.  
The Acute Abdomen in Adult Practice Dr. Claude E. Welch  
Discussion Drs. Charles B. Mixer and Jacob Fine

### SOUTH END MEDICAL CLUB

The next regular meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association 554 Columbus Avenue Boston on Tuesday April 20 at 12 noon. Dr. Norman A. Welch will speak on "The Evaluation of Some of the Modern Types of Therapy". Physicians are cordially invited to attend.

### SUFFOLK DISTRICT MEDICAL SOCIETY

The spring dinner of Suffolk District Medical Society will be given at the Harvard Club 374 Commonwealth Avenue Boston, on Saturday May 1. Cocktails will be served at

6:30 and dinner at 7:00 p.m. Mr. Gerald G. Gross editor *Washington Report on the Medical Sciences* will speak on the subject "The Prospects for Federal Medical Legislation which will be discussed by Drs. Elmer S. Bagnall and Allan M. Butler.

The ladies and members of the Massachusetts Medical Society are cordially invited. Tickets cost \$4.00 and must be purchased in advance from Dr. Richard S. Eustis 319 Longwood Avenue Boston 15 Massachusetts. Dress is optional.

### AMERICAN GYNECOLOGICAL SOCIETY

A meeting of the American Gynecological Society will be held at the Williamsburg Restoration Incorporated, Williamsburg Virginia, on May 24-25 and 26.

### AMERICAN LARYNGOLOGICAL ASSOCIATION

The sixty ninth annual meeting of the American Laryngological Association will be held at the Homestead Hotel Springs Virginia on April 14 and 15.

Members of the medical profession are cordially invited.

### AMERICAN RADIUM SOCIETY

The annual meeting of the American Radium Society will be held at the Stevens Hotel Chicago on June 20 and 21. Refresher courses and panel discussions will be presented, and the Janeway Lecture will be delivered by Sir Stanford Cade attending surgeon Westminster and Mt. Vernon Hospitals and the Radium Institute of London. His subject will be "The Achievement of Radium in the Fight Against Cancer."

Further details regarding the program may be obtained from the secretary Dr. Hugh F. Hare 605 Commonwealth Avenue Boston 15.

### SOUTHERN SURGICAL ASSOCIATION

The annual meeting of the Southern Surgical Association will be held at The Greenhner White Sulphur Springs, West Virginia on December 7-8 and 9 (secretary, Alfred Blalock M.D. The Johns Hopkins Hospital Baltimore 5 Maryland).

### AMERICAN PHYSIOTHERAPY ASSOCIATION

The annual conference of the American Physiotherapy Association will be held at the LaSalle Hotel, Chicago from May 23 to 28.

### ARIZONA STATE MEDICAL ASSOCIATION

The annual meeting of the Arizona State Medical Association will be held in Phoenix from May 19 to 21 (secretary Frank J. Milloy, M.D., 15 East Monroe Street, Phoenix Arizona).

### HAWAII TERRITORIAL MEDICAL ASSOCIATION

The annual meeting of the Hawaii Territorial Medical Association will be held in Honolulu from May 6 to 9 (secretary, H. L. Arnold Jr., M.D., Mabel Smyth Building Honolulu 53 Hawaii).

### ILLINOIS STATE MEDICAL SOCIETY

The annual meeting of the Illinois State Medical Society will be held in Chicago from May 10 to 12 (secretary Harold M. Camp M.D., 224 South Main Street Monmouth Illinois).

### KANSAS MEDICAL SOCIETY

The annual meeting of the Kansas Medical Society will be held in Wichita from May 10 to 13 (secretary D. D. Vermlison M.D., 512 New England Building Topeka Kansas).

## NEBRASKA STATE MEDICAL ASSOCIATION

The annual meeting of the Nebraska State Medical Association will be held in Lincoln from May 3 to 6 (secretary, R. B. Adams, M.D., 416 Federal Securities Building, Lincoln 8, Nebraska)

## Will's Proud of His Big Ears

*Will Dudley's mighty proud of his big ears! Best crop of corn he's grown since '38. And Will, like so many other farmers, has plenty of reason to be proud of what he raises.*

The farmer has always been a key-stone in our economic life, and the key to our national well-being. But from where I sit, he's more important now than ever. He's not only feeding America—but friends of America overseas—building good will for this country at a time when friendship for democracy is most important.

*And farmers have willingly shouldered that responsibility. Will spends extra hours in his cornfield, comes home tired to a temperate glass of beer and early bed, to be ready for the next day's work.*

From where I sit, America can be mighty grateful for her five million farmers for their productivity, hard work, temperate living—of which Will's moderate glass of beer is proof!

*Joe Marsh*

## TWO-WAY PROTECTION

### Tablets FERROSATE (Kenmore)

(Ferrous Sulfate  $\text{FeSO}_4$ )

are coated twice to provide a doubly protected Ferrous Sulfate offering these therapeutic advantages:

1. Inner coating prevents premature oxidation in vivo.
2. Outer coating increases palatability and aids in preventing tooth discoloration.

## ORTHOPEDIC APPLIANCES IN THE REHABILITATION OF PATIENTS WITH SPINAL-CORD INJURIES\*

DONALD S. BICKERS, M.D.†

BOSTON

A REVIEW of the literature dealing with the orthopedic treatment of spinal-cord injuries is remarkable chiefly for the scarcity of available reference. This deficiency is easily understandable in view of the fact that it was only with the advent of World War II that the medical profession was faced with the problem of treatment of a large group of patients with these injuries. Such cases occur sporadically in civilian life, but it is unusual for a large number to be grouped on a service devoted entirely to the treatment of problems peculiar to this type of injury. A considerable number of spinal-cord injuries, with resulting paraplegia, were incurred in World War I, but survival was the exception rather than the rule. The average length of life after such injuries is reputed to have been approximately three weeks, death being due in the majority of cases to sepsis in patients who survived initial shock. With the advent of chemotherapy, air evacuation and improved methods of treatment of shock, a high percentage of such casualties in World War II were saved for rehabilitation to a useful life. Most references and standard texts on orthopedic appliances have only an indirect bearing since they are concerned with allied but not identical problems. The long, double upright brace for the leg is discussed by Jordan,<sup>1</sup> but the concern is primarily with its use as a weight-bearing appliance rather than one designed only for splinting action as it is used in the treatment of paraplegic patients. A direct reference in the recent literature is that of Kuhn,<sup>2</sup> who mentions the brace problem in a general review of the care of such cases.

The problems presented by the paraplegic patient are unique in many ways, and one of the most important is that of braces. Proper bracing is the cornerstone on which the ambulation program is built, and ambulation plays a vital part in any compre-

hensive program designed to return such a patient to his rightful place in society. Before the factors involved in choosing the proper brace for an individual case are considered, it is necessary to establish the point in the patient's progress where braces are indicated. This turning point marks the transition from the wheelchair mobility to ambulation requiring full use of all remaining voluntary muscular power. On the Neurosurgical Service, Cushing Veterans Administration Hospital, organized generally along the lines of the Munro classification, braces are not fitted until the patient has entered Stage III. In Stage I (spinal shock), emphasis is placed on the treatment of the original injury, treatment and prevention of decubitus ulcers, bladder care, maintenance of good nutrition and intensive physiotherapy. In Stage II (diagnostic and reparative surgery) surgical procedures indicated in complications frequently incident to spinal-cord injuries are carried out. At that time, surgical closure of decubitus ulcers is done, and necessary genito-urinary surgery is completed. Bladder training, designed to give the patient twenty-four-hour bladder control, is carried on simultaneously and is usually completed at the end of this stage. In cases in which deformities develop despite all preventive measures, corrective orthopedic procedures are carried out. Of equal importance to future efficient ambulation are neurosurgical procedures designed to relieve uncontrolled muscle spasm. The importance of the proper treatment of spasm has been pointed out by a number of investigators and cannot be overemphasized. The paraplegic patient, deprived of most or all of his postural reflexes,<sup>3</sup> must develop through prolonged instruction and practice a new system of balance maintenance. This system is based on voluntary changes of posture designed to distribute body weight equally around the vertical axis of the skeletal system. The art of balance maintenance in sitting and standing is the first and basic phase of ambulation training, and upon its acquisition depends the entire success of subsequent ambulation instruction. The spasm of an even

moderately well developed mass reflex, particularly in injuries of the thoracic and cervical cord, renders this goal unattainable. The sudden, unpredictable stretch reflexes cause flexion or extension

plegic patients, frequently result when braces are forced on a markedly spastic subject. Evaluation of numerous agents and procedures for relief of spasm employed on 200 patients treated on this

of the lower extremities and trunk, with precipitate loss of balance. The result is either a fall or a rescue by the instructor, which offers a psychologic and mechanical hindrance to ambulation progress. Decubitus ulcers, an ever-present threat in para-

service over the past year indicate that the treatment of choice is the anterior rhizotomy described by Munro.<sup>4</sup> With proper indications, complete rhizotomy is done on complete cord lesions, and differential rhizotomy is done on partial cord lesions.

With these complications successfully treated, the patient is passed to Stage III (wheel-chair ambulation). It is in this relatively brief stage that the patient must first be measured for braces. Premature measurement may result in needless expense in brace alterations occasioned by changes in the nutritional status during Stages I and II. A contour tracing is made of the parts to be braced with the patient lying on a flat surface and supplemented by circumferences of extremities and trunk. The prescribed brace is then given to the patient, and he is instructed in its application in bed. When this is learned together with other basic elements of self-care, the patient is deemed ready for beginning ambulation training.

A basic premise must be borne in mind regarding the factors involved in choosing the proper brace for a given patient: the function of the brace is not the support of body weight but the maintenance of normal postural relations through splinting action. In effect, the muscle groups responsible for maintaining the body in an erect, stable position are replaced by external mechanical supports, with maximum retention of normal joint function. Three chief factors may be mentioned. The first is the level of the injury, which is usually the most important single criterion for determining the type of brace that the patient will need. When the optimal stage for brace fitting described above has been reached, there is usually a close correlation between the level of injury and the type of brace indicated. Unless otherwise indicated, all levels in the following discussion are dermatome levels. A summary of these data is presented in Table 1. In most cases the type of brace needed may be accurately determined in advance by careful muscle analysis to ascertain the existing deficit. Such tests should be done at regular intervals during the course of rehabilitation as an index of improvement, particularly in partial lesions of the cord and cauda equina. Minor variations may be indicated, and the patient must be observed in all phases of ambulation training for a proper decision to be reached. These are usually variations on a single category of brace rather than between categories — such as changes in the construction of back brace. The second factor is the severity of the injury: whether a partial or complete lesion of the cord or cauda equina. Selection of braces for complete lesions is relatively simple, but partial lesions present a greater problem since the level of injury cannot be closely correlated with the type of brace indicated. For example, a patient with a partial cord lesion at the fifth cervical segment may require a double upright leg brace with a drop-foot spring on the right, and a simple wire drop-foot brace on the left. These situations must be met individually on the basis of thorough muscle analysis and clinical observation of the patient in ambulation, the appliance that most nearly replaces the existing deficit is then chosen. The third con-

sideration comprises malformations that may be present. Most of them will be prevented or corrected surgically during the first three stages of rehabilitation, but prolonged conservative therapy may be the treatment of choice. After relief of spasm, mild hip contractures and scolioses, to mention two examples, may demand some special brace to permit corrective exercises and ambulation. These occasional complications seldom change the overall requirements of a given patient but can be met with adjustments within a basic brace pattern.

#### TYPES OF BRACES

##### *Drop-Foot or Short Leg Brace (Fig. 1)*

The specifications for the drop foot brace are as follows:

*Wire drop-foot brace.* Upright supports of 22-gauge spring steel wire are attached to the shoe, with a lightweight stirrup or pinion through the

FIGURE 1 *Wire Drop-Foot Brace (Left) Double Upright Drop-Foot Brace (Right)*

heel. The calf band is of 17-gauge spring steel, with  $\frac{3}{8}$ -inch sheet of sponge-rubber padding, covered with a calf-skin, single strap and buckle. The weight of the brace with a shoe is 1 pound, 12 ounces, and the total weight is 3 pounds, 8 ounces.

*Double upright drop-foot brace.* Steel uprights,  $\frac{5}{8}$  by  $\frac{3}{8}$ -inch, are used, with a calf band and strap similar to that of the wire drop-foot brace. A drop-foot spring is applied across a semihinged-type ankle joint, stirrup shoe attachment. The weight of the brace with a shoe is 3 pounds, and the total weight is 6 pounds.

*Indications.* Analysis of the muscles involved in control of the foot (Table 1) indicates that loss of function below the knee results from an injury to the lowest lumbar cord segments, conus or cauda equina, or all three, that involves all or part of the fourth

lumbar through the second sacral segments. Paralysis of this type are almost invariably flaccid, with considerable muscle atrophy due to damage of either the anterior-horn cell in the fourth lumbar through the second sacral segments, or to transections of all or part of the filaments of the cauda equina. Spasm is rarely a problem. This injury has been most frequently seen in patients with partial lesions of the conus and cauda secondary to penetrating

FIGURE 2 *Caliper Long Leg Brace with Detachable Drop-Foot Spring*  
Note instep bar and removable slotted plate.

wounds at or below the first lumbar vertebra. In such involvement, the function of the brace is to substitute a compensatory force for the lost dorsiflexors of the foot and, if necessary, to stabilize the ankle. The loss of the tibialis anterior, extensor digitorum longus and extensor hallucis longus will result in a drop foot with little change in ankle stability (Table 1). Such patients are adequately supported with the wire drop-foot brace, since no lateral stabilization of the ankle is required. In cases in which there is complete loss of all muscle activity below the knee, stabilization of the ankle is desirable, since such activity is normally chiefly dependent on the interaction of the muscle groups of the lateral and posterior aspects of the leg. This is best done with the double upright drop-foot brace, which provides good bilateral support of the ankle joint and positive spring drop-foot correction. In an effort to reduce the weight of the brace, the medial upright support was omitted experimentally.

The resulting abduction and eversion deformity of the foot with incomplete ankle stabilization caused us to discontinue its use. It is mentioned only for the sake of completeness and condemnation.

#### *Long Leg Braces (Fig 2 and 3)*

The specifications of long leg braces are as follows:

*Caliper with detachable drop-foot spring* Uprights,  $\frac{5}{8}$  by  $\frac{3}{16}$  inch, steel drop-ring lock, a hinged knee joint and calf and thigh bands of 17-gauge spring steel, padded with  $\frac{3}{16}$ -inch sheet sponge rubber, covered with calfskin. The ankle joint is a caliper with a detachable drop-foot spring. The drop-foot spring, with the standard attachment above, is attached below to a steel instep bar,  $\frac{3}{16}$  by  $\frac{3}{8}$  inch, by means of a detachable slotted plate fitting over a button forged on the

FIGURE 3 *Long Leg Brace with Hinged Ankle Joint and Stirrup Attachment*  
Drop-Foot Spring and Shoe Permanently Attached

end of the instep plate. The weight of each brace with a shoe is 5 pounds, 8 ounces, and the total weight of both braces with shoes is 11 pounds.

*Long leg brace with hinged ankle joint and stirrup attachment* Uprights,  $\frac{5}{8}$  by  $\frac{3}{16}$  inch, steel hinged knee joint, with a drop-ring lock. Calf and thigh bands are of 17-gauge spring steel padded with  $\frac{3}{16}$ -inch sheet sponge rubber, covered with calfskin, the drop-foot spring is permanently attached above and below on either side of a semi-hinged ankle joint. The weight of the brace with a shoe is 5 pounds, 8 ounces, and the total weight is 11 pounds.

**Indications** The chief single indication for this type of brace is loss of stability of the knees. This added factor marks the distinction between the functions performed by this brace and those of the double upright drop-foot brace. The ability to maintain the legs in extension and consequently to maintain the body in erect posture is directly dependent upon the integrity of the quadriceps femoris muscle (Table 1). Should muscle analysis and the clinical test of having the patient stand erect indicate that the activity of the muscle is lost or so weakened as to render extension of the leg inadequate, this function must be replaced by the long leg brace. These lesions occur predominantly in the lumbar cord segments, but may be due to severe or complete transections of the cauda equina at or below the level of the third lumbar vertebra. Any remaining flexors of the leg are necessarily denied their normal action at the knee by the locked knee joint and are not of primary importance in determining the type of brace used for injuries of this level. Their importance, as is any remaining function of the quadriceps femoris muscle, is in determining the type of gait the patient will use. This brace enables the patient with complete or partial loss of function from the third lumbar through the fifth sacral segment to stand erect and subsequently to learn the gait best suited to his injury. The two types of long leg brace are presented because of their relative merits and disadvantages. The first, with a detachable drop-foot spring, was devised in an effort to overcome the difficulties imposed by the caliper-stop brace while retaining the advantage of a detachable shoe. The caliper-stop brace, particularly with heavier patients and those actively engaged in ambulation, is often subject to having the drop foot recur owing to posterior bending of the stops. All the ambulation gaits, particularly the swing through, tend to cause forcible plantar flexion of the foot, stress being exerted on the stops. Similar tension is exerted when the patient ascends stairs and other obstacles, when during the course of the ascent, the toe of the foot is caught temporarily under a protruding ledge. The detachable drop-foot spring is fastened permanently above but is attached below by the slotted plate to the protruding button on the shoe after the calipers are inserted. The positive tension exerted by the properly adjusted drop-foot spring allows normal plantar flexion of the foot and has proved more effective than stops in correcting the drop foot. The spring should be parallel to its supporting lateral upright to reduce the tendency to eversion and abduction of the foot, which may result if the mechanical advantage is too great. Furthermore, the spring must be properly adjusted to prevent over-correction. The chief advantages derived are the convenience in application and removal, without the necessity of removing the shoes, and continued drop-foot correction. The advantage of the second type of brace is the slight increase in

lateral stability of the ankle with the same good drop-foot correction. The hinge may be so constructed as to allow plantar flexion of the feet. The obvious disadvantage of this brace is the greater difficulty of application and removal and the necessity for removing shoes and braces simultaneously. In the use of either of these braces, three points of clinical importance should be emphasized. The hinged ankle joint should be placed 1 cm. above the tip of the lateral malleolus in line with the transverse axis of the talotibial joint. The knee joint should be placed opposite the midpoint of the medial and lateral condyles of the femur (the points of emergence of the transverse axis of the knee joint).

FIGURE 4 Long Leg Brace with Pelvic Band.

Hip joint is a freely movable hinge. Construction of the brace is the same as that in Figure 2.

If the knee joint is placed too high, it will be noted on sitting that the thigh bands are displaced anteriorly and tend to cut into the soft tissues of the posterior surface of the thigh. The reverse is true when the joints are too low. Lower ends of the uprights that are excessively high may tear the patient's clothing when worn under street clothes. There is a tendency, though less marked, for similar pressure to be exerted on the leg with a displaced hinged ankle joint. Care should be exercised in determining the height of thigh bands, since excessive height may cause the formation of decubitus ulcers over the ischial tuberosities and undue pressure on the perineum and genitalia. The superior edge of the band should be parallel to the inguinal

ligament and just low enough to clear those vulnerable structures

### *Long Leg Brace with Pelvic Band (Fig 4)*

The specifications of the long leg brace with pelvic band are as follows

*Long leg braces with uprights of  $\frac{5}{8}$ -by- $\frac{3}{16}$ -inch steel*  
The upright of the pelvic-band attachment is made of  $\frac{5}{8}$ -by- $\frac{3}{16}$ -inch steel, with calf, thigh and pelvic bands of 17-gauge spring steel, padded with  $\frac{3}{16}$ -inch sheet sponge rubber covered with calfskin. The ankle joint is of the caliper type, the knee joint a drop-ring lock-hinge joint, and hip joint a free hinge joint allowing ante flexion and retro flexion at the hip. The drop-foot spring is fixed above and is detachable at the shoe by means of a slotted plate over the button of the instep bar. The pelvic band is secured by a single padded leather strap. The weight of the brace with shoes is 12 pounds, 9 ounces.

*Indications* Analysis of component parts of this brace indicates that the only additional feature, compared with the long leg brace, is the pelvic band. This is attached by an increase in the length of the lateral uprights of the long leg braces and fastening of the band uprights with a freely movable hip joint. No lock is attached. Its adoption for the paraplegic patient is based on specific indications. The level of the injury (Table 1) corresponds roughly to the same level indicating the double upright long leg brace described above. Injuries from the third lumbar segment or cauda equina, or both, that are so complete as to deprive the patient of the functions discussed above under the indications for the long leg brace will in some cases require the pelvic-band extension. The same foot and ankle support is needed, as well as the capacity to maintain the knee in extension in a standing position. The additional factor involved is the loss of part or all of the function of the internal and external rotators of the thigh. The rotation deformities occasioned by the loss of these muscles comprise the chief indication for the pelvic-band extension. The loss of the external thigh rotators with some remaining function of the internal rotators results in a medial rotation deformity of the lower extremities if long leg braces alone are used. This position renders it difficult for the patient during ambulation to swing through smoothly and to regain balance properly. Conversely, unopposed external rotation of the extremities, with resulting external rotation of the feet, interferes even more with these maneuvers. The specific function of the pelvic band is to correct this muscular imbalance by fixing the lower extremities in the proper anteroposterior alignment of 5° external rotation. As would be expected, no appreciable lateral stabilization of the hips can be obtained with the pelvic band, since the chief point

of such instability in high lesions is in the lumbar portion of the spine. It may be possible to determine the need for the addition of a pelvic band only by clinical study of the patient's ability to maintain proper alignment of the lower extremities in ambulation. It is essential that no lock be placed on the hip joint, since the normal hip-joint action must be preserved regardless of the gait used. The hip joint of the brace must be placed at the proper level to obtain maximum function of that joint. Its position should be opposite the superior border of the greater trochanter, which is the point of exit of the transverse axis of the hip joint. When the joint is too high, there is downward traction on the pelvic band, as well as undue pressure on the anterior aspect of the thigh by the thigh band when the patient is in the sitting position. If the joint is placed too low, there is upward thrust on the pelvic band and pressure on the posterior aspect of the thigh. The pelvic band should fall midway between the crest of the ilium and the greater trochanter to avoid pressure over the bony prominences, with possible decubitus-ulcer formation. The comfort of the patient must also be considered with injuries of this level since the sensory level is usually below the point of contact with the band.

### *Long Leg Braces with Back-Brace Attachments (Fig 5 and 6)*

The specifications of these braces are as follows

*Long leg brace and lateral supports of back brace*  
are of steel,  $\frac{5}{8}$  by  $\frac{3}{16}$  inch, with calf and thigh bands of 17-gauge spring steel, a back band of 17-gauge spring steel or duraluminum, padded with a  $\frac{3}{16}$ -inch sponge rubber covered with calfskin. The ankle joint is of the caliper type with detachable drop-foot springs. The knee joint has a drop-ring lock, with a hinge joint, and the hip joint is of the freely movable hinge type, abdominal support is provided by a piece of 11-ounce duck with multiple canvas web straps.

*Indications* This type of brace is limited to the highest levels of injury — that is, generally, those above the third lumbar vertebra (Table 1). Its distinguishing feature is lateral hip stabilization by functional replacement of muscle groups controlling the actions of the pelvis and lumbar spine. The degree of impairment of these muscle groups depends upon the level and completeness of the injury. If muscle analysis indicates deficiency of clinical importance, support must be sought to replace the following vital functions: maintenance of erect posture of the trunk, lateral stability of the pelvis and lumbar spine and maintenance of the normal pelvic inclination. The first of these functions is performed by the iliocostalis lumborum, longissimus dorsi and quadratus lumborum, which are pre-

dominantly innervated by the first four lumbar segments. They also act as lateral flexors by contraction of the homolateral group with the simultaneous relaxation of the contralateral group. Although the intrinsic muscles surrounding the hip joints contribute appreciably to pelvic stability, the lumbosacral group appears clinically more important. The flexors of the pelvis and lumbar spine have a dual function to perform and would be completely lost in a lesion at the level of the sixth thoracic segment or higher. They not only are important as flexors of the lumbar spine but also interact with the extensors of the pelvis and lumbar spine to maintain the normal angle of pelvic inclination. This angle, formed between the true conjugate and the horizontal with the patient in the standing position, is normally 50 to 60°. Loss of these two opposed groups results in lumbar lordosis, with marked in-

creased tension after completing the swing through while lifting his crutches forward to begin the next swing through. The ability to get the hips forward after completion of one swing through in preparation for the next is essential for efficient swing-through ambulation regardless of the type of brace employed.

It is with the use of this brace that the necessity for proper preambulation therapy becomes most evident. Spasm of muscles acting on the thigh, pelvis and trunk must be relieved. Otherwise, the patient will be subject to sudden "jacking" forward or backward as the result of a mass reflex initiated by stretching of these muscles in the act of swinging. The patient must have completed the basic maneuver of balance, since it is particularly important in lesions of this level that this stability and feeling of confidence be acquired. Should all medical therapy of a well developed mass reflex fail and the patient refuse surgical correction, this type of brace cannot be employed, and consequently the most efficient ambulation cannot be attained. The alternative is the long leg brace with pelvic band with hip locks and a wider abdominal support. This combination allows the patient to substitute flexion and

FIGURE 5 Long Leg Brace with Back Attachment (Front View)  
Hip joint is a freely movable hinge. Construction of the brace is the same as that in Figure 2.

crease in the angle of pelvic inclination. This lordosis is quite disabling and virtually prohibits the attainment of balance and subsequent ambulation. The back brace is designed to maintain extension of the trunk by articulation with the thoracic cage above and the lateral long leg supports below. The pelvic extension produced by the inferior transverse portion of the back attachment, together with the replacement of the abdominal musculature function by the abdominal support,<sup>4</sup> tends to maintain the normal pelvic inclination. Side sway at the hips is

FIGURE 6 Long Leg Brace with Back Attachment (Rear View)

tension after completing the swing through while lifting his crutches forward to begin the next swing through. The ability to get the hips forward after completion of one swing through in preparation for the next is essential for efficient swing-through ambulation regardless of the type of brace employed.

It is with the use of this brace that the necessity for proper preambulation therapy becomes most evident. Spasm of muscles acting on the thigh, pelvis and trunk must be relieved. Otherwise, the patient will be subject to sudden "jacking" forward or backward as the result of a mass reflex initiated by stretching of these muscles in the act of swinging. The patient must have completed the basic maneuver of balance, since it is particularly important in lesions of this level that this stability and feeling of confidence be acquired. Should all medical therapy of a well developed mass reflex fail and the patient refuse surgical correction, this type of brace cannot be employed, and consequently the most efficient ambulation cannot be attained. The alternative is the long leg brace with pelvic band with hip locks and a wider abdominal support. This combination allows the patient to substitute flexion and

extension in the lumbar spine for normal hip motion while splinted by his spastic muscles. This is not efficient ambulation and is never recommended as the procedure of choice, but only as a last resort under these circumstances.

The height of the back brace has been the subject of much discussion and experiment, but the optimum level has proved to be 4 cm. below the inferior angle of the scapulas. This is sufficiently high to allow good articulation with the lower portion of the thoracic cage and yet low enough to permit free action of the scapulas and other elements of the pectoral girdle. Higher back braces are superfluous since the thoracic cage is well supported structurally by ligaments and the pectoral girdle. A positive objection to braces extending above this point is the

ward. Unless a caliper lock is employed in addition to stabilize this ankle joint, some stability may be sacrificed. This is justifiable since it means the difference between a brace that is practicable for use and one that is not.

### Miscellaneous (Fig 7)

In patients whose injuries occur above the first thoracic segment, certain special appliances may be made for the arms, depending upon the degree of brachial-plexus involvement. Among these are the triceps brace to maintain the arms in extension and a leather wristlet to maintain wrist stability. The knee strap is used when necessary to prevent genu varus or valgus, and the "T" strap performs a similar function at the ankle joint. The cock-up splint is made of a wire frame with transverse canvas web supports.<sup>7</sup> The sleeper brace and cock-up splints are used in the earlier stages (I and II) before the patient becomes ambulatory as an aid in preventing flexion contractures of the ankle and knee. The detachable spreader bar is occasionally employed in teaching the swing through in Stage IV, but further use is discouraged, it is attached to the medial uprights at ankle level by means of bolts with wing nuts. The Taylor back brace, not shown, is used for correction in the occasional case in which severe kyphosis develops in high thoracic and cervical injuries.

### DISCUSSION

It will be noted in the foregoing discussion of the four general types of supports that the indications are based primarily on the assumption of a complete lesion at the level indicated. Although such an injury is actually present in the majority of patients, a smaller proportion of incomplete injuries of the cord and cauda equina will be encountered. In such cases it is impossible to state categorically in advance exactly what type of appliance will be indicated, not only because of wide variance in the initial pattern of muscular dysfunction but also because there may be gradual improvement in muscular power over a period of months after the initial trauma. Muscle analysis is indispensable in partial lesions as the initial step when the patient is ready for bracing. With this information at hand and the specific function performed by each type of appliance borne in mind, a rational approach may be made to the specific problem presented. In cervical-cord injuries the extent of the brachial-plexus involvement will determine the appliances necessary for the upper extremities.

Although a detailed study of ambulation is beyond the scope of this communication, it is essential in any discussion of braces at least to mention the type of gait that may reasonably be employed with a given appliance. Patients requiring only drop-foot braces approach most nearly the normal gait. They may use ultimately either one or two canes and walk

FIGURE 7 Miscellaneous Braces

interference offered to the proper use of crutches, which become entangled with the back-brace extension. The height has a direct bearing on the total weight, which at best exceeds that of any other type. Attempts to substitute duraluminum for the uprights and transverse struts of the back brace have resulted in failure because of the great stress that the appliance is called on to bear. Some weight may be spared with substitution of sheet duraluminum for the 17-gauge steel in the main body of the back support, but further use of this material is foredoomed to failure.

It was primarily for patients with back braces that the caliper with a detachable drop-foot spring was developed, since the stirrup-type leg brace with shoes and back brace attached requires the assistance of one or two persons in application and removal of the unwieldy device. With calipers and a detachable drop-foot spring the patient can wear shoes continually, insert the calipers into the shoes and then proceed to lace the brace from below up-

almost normally except that they tend to proceed on a rather wide base with steppage gait. Initially, it may be necessary to train such patients with crutches instead of canes, but the use of crutches should be discouraged as rapidly as possible — the obvious objections to crutches are that they call attention to the patient's handicap and promote a feeling of dependency. The type of gait to be employed by patients with long leg braces will depend on the degree of function remaining in the thigh flexors. Should the thigh flexors be adequate to advance the legs even though not strong enough to support the patient's body weight, either the four-point or the more rapid two-point crutch gait is feasible. In either case, he should also be taught the swing through, which is the most rapid of all gaits and may be required in situations in which speed is desirable, as in crossing streets with traffic lights. This type of gait can be taught to any properly prepared patient with a complete or partial lesion below the first thoracic segment and is mandatory for those with loss of thigh flexors and higher lesions (the second lumbar segment upward). The pelvic-band group will not usually exhibit enough function to allow the two-point and four-point gaits and consequently must be taught the swing through with the preliminary temporary swing-to gait. For patients requiring back braces the only practicable gait for distance walking is the swing through, which is taught to all patients except those with lesions above the second thoracic segment that are so severe as to cause gross impairment of arm function. As in the pelvic band group, the swing to is taught as a preliminary to learning the swing through. The swing to is retained only for maneuvering in close quarters where the lack of space renders the swing through impossible. Since the hip joint must be movable for efficient ambulation, it is incumbent on these patients to exercise more skill and balance than lower injuries demand. The patient should not be permitted to attempt a swing to until he has thoroughly mastered the art of balancing with first one and then the other crutch off the floor, unsupported by either an instructor or other artificial means. The poise and sense of confidence gained thereby is basic in the subsequent steps of ambulation progressing through the swing to to an efficient swing through. Lesions high enough to involve the brachial plexus usually force the patient to walk with a swing to or shuffle. This has proved practicable with one of our patients with a complete motor lesion below the fifth cervical segment except for some intact fibers in the seventh and eighth cervical segments. Concurrently and later, all patients must go through a period of intensive mat work and other calisthenics designed to strengthen the pectoral girdle and arms to a point that will permit the stress of weight bearing demanded for ambulation. This is particularly important in the group with higher injuries.

The knee lock used in construction of the long leg braces is recommended after testing of several more complicated types. It is of simple, rugged construction requiring a minimum of machining and repair. The gravity lock is easily placed and fool-proof during use. More elaborate locks are more expensive and prone to damage by twisting or bending.

The width of calf and thigh bands is of practical importance. As a general rule, best results are obtained from narrow bands. Although no difficulties have been encountered, owing to the youth of the patients, circulatory embarrassment may well result in older patients if calf and thigh bands are too wide. This precaution should apply to any patient with venous varicosities, arteriosclerotic changes or other impairment of peripheral circulation.

Steel is the material of choice though its weight is somewhat greater than that of duraluminum. Its durability and capacity to withstand torsion and stress, particularly of the higher braces and in heavy patients, make it irreplaceable by any of the light alloys available. Observations on duraluminum braces constructed here and at other institutions indicate that joints deteriorate rapidly and that twisting necessitates frequent attempts at adjustment, which are rarely, if ever, successful. The calf and thigh bands used on these braces are not of the contour-fitting type advocated by Hessing,<sup>1</sup> since no weight-bearing function is required of them. The considerable time and expense associated with the building of such braces may be avoided.

#### SUMMARY

Preliminary rehabilitation procedures prior to the fitting of braces on patients with spinal-cord injuries are outlined.

Factors involved in choosing the proper brace for patients with spinal-cord injuries, with special reference to the level of injury, are discussed.

Four main types of brace are presented in detail, with the indications for each.

The type of gait to be expected for each level is described.

I am indebted to Mr. Walter Gavin of the Orthopedic Shop, Cushing Veterans Administration Hospital, for his co-operation and assistance.

# ULCEROGLANDULAR TULAREMIA TREATED WITH STREPTOMYCIN

## A Report of Two Cases

CAPTAIN RAYMOND E. LESSER, M C, A. U. S., AND MAJOR SIDNEY MILLER, M C, A. U. S.

HEILMAN'S<sup>1</sup> demonstration of the effectiveness of streptomycin against *Pasteurella tularensis* in vitro and in vivo has found application in the treatment of tularemia in man. The cases presented below are considered to be of interest because they report additional experience with the use of streptomycin in the treatment of tularemia. Furthermore, they afford an interesting comparison of the effectiveness of treatment of the acute and chronic phases of the disease.

### CASE REPORTS

**CASE 1** A 39-year-old man was hospitalized on February 14, 1947, complaining of "cold sensations," pain in the eyes and back and coughing and sneezing of 2 days' duration.

The past history as obtained at the time of admission was of no related significance except for typhoid fever 29 years previously and malaria in 1930.

Physical examination revealed a haggard but well nourished man who appeared moderately ill. The skin was livid

scratched his right middle finger with a briar, but he had not skinned the rabbits. On the following day a localized area of infection was noted at the site. On the day of admission he experienced chills, fever, headache, general malaise and a tender swelling in the right axilla. He also volunteered the information that "rabbit fever, typhus fever and hemorrhagic fever" were endemic in his home town, Americus, Georgia, the locale of his rabbit hunting. Agglutinations and a culture and smear of the ulcerated area were made, and streptomycin—in a dosage of 3 gm daily—was given. Treatment was continued for 7 days. Within 24 hours the patient experienced dramatic subjective improvement, and in 48 hours the temperature began to regress and the lesion to undergo involution. At the end of 7 days the temperature became normal and remained so for the duration of the hospital stay of 54 days. The local lesion and axillary adenopathy completely subsided 4 weeks after the institution of streptomycin.

The subsequent clinical course was uneventful. The pertinent laboratory data are summarized below, and the clinical course is graphically represented in Figure 1.

On February 14 examination of the blood disclosed a white-cell count of 12,000, with 70 per cent neutrophils, 23 per cent lymphocytes and 7 per cent monocytes. The urine was normal. The blood Kahn test was negative. On February 25 a blood culture was negative, and smear and culture of the ulcer were negative for *Past. tularensis*, agglutinations for the organisms of typhoid, paratyphoid and non-dulant fever, as well as those for salmonella and typhus (proctus x 19), were negative. Agglutinations for *Past. tularensis* were +++++ in a dilution of 1:40, +++ in one of 1:80 and negative in one of 1:160. On March 6 the agglutination was +++++ in a dilution of 1:1280, ++ in one of 1:2560 and negative in one of 1:5120. On March 10 the agglutination was +++++ in a dilution of 1:160 and ++ in one of 1:1280. On March 19 the agglutination was +++++ in a dilution of 1:320, ++ in one of 1:640 and negative in one of 1:1280, and on April 7 it was +++++ in a dilution of 1:160, ++ in one of 1:640 and negative in one of 1:1280.

Three x-ray examinations of the chest during the initial 10-day period were negative.

**CASE 2** A 26-year-old paratrooper was hospitalized on April 24, 1946. He complained of right axillary and right epitrochlear swelling associated with numbness of the fourth and fifth fingers of the right hand of 2 months' duration. During that time he had lost 17 pounds in weight and had observed that the "swellings" had been increasing in size, at the time of admission they had become painful. The patient had been rabbit hunting in January, previous to and at the time of which he had had a "sore" on the ring finger of the right hand. After he dressed the rabbits the "sore" on the right ring finger became deeply infected, and red streak extended to the wrist. Two weeks later he experienced chill and fever. After these symptoms had persisted for 1 week he reported to another Army installation, where he was treated for malaria, the fever persisting for 1 week after hospitalization. On the day of admission he had noted the onset of aching in the muscles and joints.

Physical examination revealed a well developed man, who showed signs of recent weight loss. There were numerous small, nontender shotty lymph nodes in the anterior cervical triangle. In the right axilla there were three tender nodes which were rubbery in consistence and measured 1 or 2 cm in diameter. A similar tender right epitrochlear node was present. When palpated, a linear structure that was considered to be the ulnar nerve moved on manipulation of the node and produced a shocking type of ulnar paresthesia. An ulnar hypesthesia of the fourth and fifth fingers was also present. A circular scar, measuring 5 mm in diameter, was on the medial dorsal surface of the terminal phalanx of the fourth finger of the right hand.

FIGURE 1 Pertinent Laboratory Data and Clinical Course in Case 1

Except for a moderately injected throat and increased breath sounds at the left base, the findings were not remarkable.

On the following day the patient began to manifest a spiking, remittent type of fever. The examining ward officer believed that the patient had a virus pneumonia. When the temperature continued and coarse rales were noted at the left base, previous supportive and symptomatic measures were supplemented by 300,000 units of calcium penicillin in beeswax and peanut oil each day. Despite this therapy the clinical course remained unchanged. Two weeks after admission the examining ward officer first noted an umbilicated, ulcerative lesion with a necrotic center on the dorsal surface of the right middle finger at the distal phalangeal joint, measuring 1.5 cm in diameter. The edges were raised, erythematous and indurated. A single tender, firm lymph node measuring approximately 3 cm in its greatest diameter was palpable in the right axilla. The presumptive diagnosis of tularemia was entertained, and corroborative studies were made.

Further questioning revealed that the patient had been rabbit hunting 3 days before admission. He stated he had

Examination of the blood disclosed a white-cell count of 7500, with 55 per cent neutrophils. A smear was negative for malaria. The urine and the serologic findings were normal. The corrected sedimentation rate was 11 mm. in 1 hour (Wintrobe method). Two agglutinations for *Past. tularensis* were negative. The presumptive diagnosis of tularemia was so strongly held that it was requested that the specimen be sent to the Service Command Laboratory where agglutinations for *Past. tularensis* were reported + + + + in a dilution of 1:320, and + + in one of 1:2560. X-ray examination of the chest was negative.

During the hospital stay the patient was afebrile. With the establishment of the diagnosis of tularemia streptomycin therapy consisting of 0.2 gm. every 4 hours for a total of 4.4 gm over a 4-day period was instituted. During treatment

There was generalized lymph node enlargement, a 1-cm., nontender right axillary node, several pea-sized, tender left axillary nodes, two pea-sized, nontender right epitrochlear nodes, three similar nontender left epitrochlear nodes and bilateral tender inguinal nodes on the left.

The temperature was 97.6°F., the pulse 80 and the blood pressure 110/85.

The patient remained afebrile throughout the hospital stay. Shortly after admission the left epitrochlear and left inguinal lymph nodes were surgically removed. The former was extracted and cultured on cystine blood agar. However, no growth was obtained. The inguinal node was sent to the area pathology laboratory which reported chronic lymphadenitis. X-ray examination of the left hip was negative.

Because of the rise in agglutination titer as well as the significant change in clinical course it was believed that the

\*Streptomycin, in total dosage of 4.4 gm., given between May 11 and 15

†Streptomycin, in total dosage of 12.0 gm., given between March 4 and 11

there was beginning regression of the lymphadenopathy and diminution in the weakness. One week later all tenderness of the lymph nodes had subsided but slight residual adenopathy remained. The patient, who was much improved subjectively, was discharged to duty 35 days after admission.

After discharge he was seen periodically as an outpatient. Objective and subjective improvement continued, with complete resolution of the adenopathy and with ability to carry on with military performance. However, he still complained of some weakness and did not completely regain the weight that he had lost.

Determinations of agglutination for *Past. tularensis* were made monthly and remained constantly + + + + in a dilution of 1:160 during the ensuing months.

Except for weakness and nausea following exertion the patient remained well until December. He experienced a mild aching sensation in the left thigh, left leg and left lower quadrant. When he arose each morning associated malaise returned. The symptoms were of gradual onset but increased severity. On January 6, 1947 he noted for the first time a recurrence of lymphadenopathy in the left epitrochlear region. At the unit dispensary an agglutination for *Past. tularensis* was reported as + + + + in a dilution of 1:1280—a higher titer than at any time previously or subsequently in the illness. On February 3 the aching pain in the left axilla and left leg became severe. The leg pain apparently originated in the left inguinal region and was associated with left inguinal adenopathy; the pains radiated down the leg, were aggravated by exercise and were relatively constant. A novocain injection into the left groin produced relief for 1 hour. Neuropsychiatric examination revealed no psychoneurotic tendencies.

On February 24 the patient was readmitted to the hospital because of the symptoms and clinical course described above. Physical examination revealed a slightly toxic and chronically but not seriously ill patient.

patient was experiencing a relapse. Therefore, on March 4 streptomycin was started consisting of 3 gm. daily for 7 days in divided doses for a total of 21 gm. At the conclusion of therapy the patient felt markedly improved and the adenopathy slowly regressed. Previously, he had lost 15 pounds in weight. One month after the conclusion of therapy he had regained 7 pounds. There was no adenopathy, and the agglutination determination was + + + + in a dilution of 1:160 and + + in one of 1:320. However the last determinations were + + + + and + + in dilutions of 1:160 and 1:640 respectively on May 26. Urinalyses were negative during the period of observation. An electrocardiogram was normal. A bromsulphalein test (5 mg dose) showed no retention of the dye in 1 hour. The corrected sedimentation rate was 9 mm. in 1 hour (Wintrobe method) on two occasions.

The agglutination determinations are presented in Table 1

## DISCUSSION

The effectiveness of streptomycin treatment in the cases reported above parallels that which has appeared in the literature to date.<sup>1-12</sup>

Case 1 afforded no particular problem once the diagnosis had been established. The response was excellent, so far as both morbidity and mortality were concerned, and the effectiveness of streptomycin was again demonstrated. Case 2, however, presented a more complex problem.

Several features present themselves for discussion. The effectiveness of streptomycin when latency exists between initial onset of the disease and the institution of treatment does not seem to be en-

hanced Although the clinical response to streptomycin was definite, the subsequent course of the disease indicates probable inadequacy of dosage initially It may also indicate decreased effectiveness of treatment when a delay occurs between the initial phase of the disease and the institution of therapy The recurrence of symptoms associated with variation in serologic titer of significant degree suggests that criteria for chronicity should be extended farther than the number of days of temperature above 98.6°F, the duration of buboes and the number of days in bed, as suggested by Foshay and Pasternak.<sup>6</sup> Evidence for relapse as manifested by serologic and clinical changes may be correlated with the retention of living bacteria within the recovered patient The inability of streptomycin to effect lasting remission in Case 2 was probably due not only to this fact but also to development of resistance by the organism to the antibiotic agent The initial amount of streptomycin used may be considered inadequate in the light of current knowledge of organism sensitivity It is unfortunate that such studies were not available in this case, in which the course of events suggests the importance of early control of the disease before maximum invasion has occurred

## SUMMARY

Two cases of ulceroglandular tularemia treated with streptomycin are presented in which the course paralleled that which has appeared in the literature to date

The mechanics for failure to effect a lasting cure in one case are discussed

## THE EFFECT OF SURGICAL OPERATIONS ON THE BROMSULFALEIN-RETENTION TEST\*

HENRY J. TAGNON, M.D.,† GUY F. ROBBINS, M.D.,‡ AND MARY P. NICHOLS, A.B.

NEW YORK CITY

THERE are several reports in the literature dealing with the effect of surgical operations on liver function. The available material was recently reviewed.<sup>1,2</sup> Most workers report changes in a high proportion of patients after surgery under general or spinal anesthesia. The hippuric acid test was used in several cases but has been criticized on theoretical grounds. The principal objection is that it depends on the integrity of kidney function, which may be impaired immediately after a surgical operation. Other authors have reported results obtained with the bromsulfalein-retention test using an injection of 2 mg. of the dye per kilogram of body weight.<sup>2</sup> It has recently been shown that the bromsulfalein-retention test is rendered more sensitive by the use of a dose of 5 mg. per kilogram of body weight.<sup>3</sup> Finally, in view of the report that mechanical trauma to the liver may produce impairment of its function,<sup>4</sup> it seemed worth while to evaluate the effect on the liver of extra-abdominal operation so as to exclude the possible factor of mechanical trauma.

The work reported below represents an attempt to detect changes in the function of the liver following extra-abdominal operations by means of the bromsulfalein-retention test modified so as to make it more sensitive.

In addition to this procedure blood was obtained for thymol-turbidity and cephalin-flocculation tests.

Bromsulfalein retention was determined on non-fasting patients according to the method of Mateer et al.,<sup>3</sup> 5 mg. per kilogram of body weight and a thirty-minute period being used. Readings of bromsulfalein retention were made by comparator block<sup>5</sup> matching.

The cephalin-flocculation test was done by the method of Hanger,<sup>6</sup> using the Difco reagent. A single twenty-four-hour reading of the reaction was recorded.

In the thymol-turbidity test the technic described by MacLagan<sup>6</sup> was used and the values expressed in cubic centimeters of a suspension of barium sulfate as recommended by Ley et al.<sup>7</sup> The reaction of the thymol reagent as measured by the Beckman electrometer was pH 7.8.

\*From the Sloan-Kettering Institute for Cancer Research and the Memorial Hospital for the Treatment of Cancer and Allied Diseases.

†Senior fellow, National Research Council.

‡National Cancer Institute surgical fellow.

<sup>5</sup>Kindly supplied by Hynson, Westcott and Dunning, Philadelphia. With 5 mg. of dye per kilogram of body weight, a correction factor is used in the readings.

### MATERIAL AND METHOD

A group of 20 patients admitted to the Memorial Hospital for operative treatment was studied. Half the patients (Group I) were on the Head and Neck Service, and the other half (Group II) on the Breast Service. This type of patient was selected to avoid the inclusion of cases in which intra-abdominal procedures had been performed. The possibility of mechanical trauma to the liver was therefore excluded. In each group of 10, the patients were unselected and were studied as they were admitted on the wards.

The state of nutrition of each patient was appraised by means of the history and general appearance, the weight and the detection of clinical signs of nutritional deficiencies. All patients studied were found to be in a satisfactory state of nutrition except 1 (Case 7), who was obese. Clinical evaluation of pre-existing liver damage was done by questioning about the existence of past liver disease, exposure to toxic factors including alcoholism and the detection by physical examination of such signs as enlargement of the liver and spleen, icterus, collateral circulation and spider angiomas. By these criteria, all patients were found to be free of clinically detectable liver disease before and after the operation period except 1 (Case 2), whose liver was slightly enlarged and who had a past history of heavy alcoholic intake.

Two patients, Cases 12 and 14, were found to have high blood pressure on admission. The former had a blood pressure of 170 systolic, 120 diastolic, auricular fibrillation and slight dyspnea on exertion, but no peripheral edema. Functionally she belonged to Group II-C of the classification of the New York Heart Association, her cardiac status was not clinically altered by the operative procedure. The other patient had a blood pressure of 210 systolic, 90 diastolic. Her only cardiac symptom was slight dyspnea on exertion. This case should be considered in Group I-B of the classification of the New York Heart Association, the operation did not alter her cardiac status.

The over-all clinical picture, including the type of operation and its duration, is presented in Table I. Some patients (Cases 1 to 10) received intravenous pentothal sodium as a general anesthetic, in others (Cases 11 to 20) operation was performed under general anesthesia by nitrous oxide, oxygen and ether. Every patient prior to operation received an injection of 15 mg. of morphine, 0.6 mg. of atropin and 100 mg. of nembutal or 100 mg. of luminal.

In each group the patients were classified according to decreasing severity of operation. Thus in Group I, the most serious operation was performed in Case 1, and the least serious in Case 10. In Group II the most serious operation was performed in Case 11, and the least serious in Case 20. Evaluation of the gravity of the surgical procedure is

admittedly arbitrary and was based mainly on two criteria: extent of trauma, with particular emphasis on bone resection, and duration of the procedure. This classification does not pretend to be an absolute one but rather reflects the general trend of severity within each group.

The blood pressure was followed by readings obtained at fifteen-minute intervals during the entire procedure and immediately thereafter. A fall of blood pressure of 20 to 40 for not longer than half an hour was considered a sign of mild shock. A more serious manifestation of shock was not observed. Replacement fluids given in the course of the operation are indicated in Table I. Fever was absent at the time of operation in all patients.

On admission the bromsulfalein-retention test was carried out, and blood was obtained for the thymol-turbidity and cephalin-flocculation tests. This procedure was repeated within an hour of the patient's return from the operating room. In most cases the patient was still under the influence of the anesthetic when the second test was done. At least a one-day interval separated the preoperative and postoperative tests. The patient was tested again once or twice several days later when he was well on the way to recovery.

### RESULTS

#### *Bromsulfalein Clearance*

Before the operation the retention of bromsulfalein in all patients did not exceed 10 per cent, with the exception of 1 patient (Case 7), who had a retention of 12 per cent. The upper limit of normal retention of bromsulfalein after thirty minutes with the technic used is 10 per cent, and all patients studied can therefore be considered as having had a normal test preoperatively.

Immediately after the operation, there was a marked elevation of the amount of bromsulfalein retained in the blood in several patients; the increased retention could be considered significant in Cases 1 to 9, 11, 12, 14, 15 and 16. The elevation was absent or insignificant in the others. The increased retention was pronounced in 6 cases in Group I (Cases 1, 2, 3, 5, 7 and 8), the greatest retention being observed in Case 8, and in 2 patients in Group II (Cases 11 and 12). The increased retention was not maintained, and the test returned toward normal in the following days.

#### *Thymol Turbidity*

The usually accepted upper limit of normal with this test is a turbidity corresponding to 1.75 cc. of barium sulfate suspension. Four of the 20 patients initially had a somewhat elevated test (Cases 1, 11, 14 and 20). There was no general increase after the operation. One patient (Case 7) showed a

significant increase. In the others the thymol turbidity either remained unchanged or decreased.

### *Cephalin Flocculation*

A normal test is represented by absence of flocculation (0) or a + reaction. Five patients (Cases 1, 4, 5, 8 and 10) had an abnormal flocculation test preoperatively. The change in cephalin flocculation postoperatively was not consistent, increasing in some patients and decreasing in others. Most patients in Group II, with the exception of Case 19,

In Group I there was no absolute correlation between the severity of the operation and the amount of dye retained postoperatively. For instance, the patient (Case 8) whose operation was considered less severe than that on the 7 patients preceding her in the classification of Table 1 had the highest degree of retention. In Group II the correlation was better, since the greatest retention of dye was observed in the first patients of the group (Cases 11 and 12). If the two groups of patients are considered together, there seemed to

had a normal cephalin flocculation initially, which remained normal postoperatively.

### DISCUSSION

The data show that in 14 of the 20 patients there was a significant increase in the retention of bromsulfalein postoperatively as compared to the amount retained before the operation. The retention of dye was very pronounced in several cases. Whereas all patients, with the possible exception of 1 (Case 7), initially had a normal clearance, the increased retention following the operation in 14 cases resulted in postoperative values that were considered abnormal and indicative of liver dysfunction.

be a correlation between severity of operation and retention of dye, since the last patients of Group II, who probably underwent the least severe type of surgical procedure, also showed the smallest degree of retention postoperatively.

It is obvious that the criteria by which the severity of the operations was evaluated are not absolute, and other factors than the ones considered above may have played a role.

The mechanism by which a surgical operation produces such marked changes in bromsulfalein retention is not entirely clear. Liver dysfunction is a conspicuous and early sign of shock.<sup>8</sup> The early stages of shock may not be manifested by a fall of blood pressure at a time when anoxemia of internal

organs such as the liver and the kidney has already taken place.<sup>9</sup> It is therefore conceivable that although the patients in this series either did not experience a fall in blood pressure or at most showed a slight and transitory fall, they had a certain degree of anoxemia of the liver during the operation, explaining the reduced ability of this organ to clear the blood of dye. In that case, the increased retention of bromsulfalein following an operation might be significant as a measure of the amount of injury inflicted on internal organs by a surgical procedure.

If the changes in bromsulfalein retention observed denoted liver dysfunction, the abnormality appeared to be reversible and did not persist longer than a few days. Normal or nearly normal values were observed in almost all patients a few days after the operation.

So far as the thymol turbidity and cephalin flocculation were concerned, it was not expected that the tests would show any significant change. These procedures depend entirely on the presence of an abnormal globulin constituent in blood plasma, and

applied to a distant anatomic region. A direct mechanical trauma to the liver during the operation, as in the course of an intra-abdominal operation, seems to be ruled out in the patients of this series by the type of subjects selected.

The anesthesia may have been a contributory factor, although pentothal and ether are not considered to be liver poisons. Nevertheless, this factor cannot be entirely ruled out. The extent of the surgical procedure and its duration, regardless of the type of anesthesia, appeared to be more important. The data do not indicate that the age of the patients was a decisive factor in the production of postoperative liver dysfunction as shown by the retention of bromsulfalein in the blood.

this could hardly be expected to occur during the relatively short duration of the operation. The absence of definite changes in the two tests during the postoperative period indicates that the liver dysfunction detected by the bromsulfalein test in the series of patients studied was not pronounced, and confirms its transitory nature.

These results largely confirm those obtained by previous workers and indicate definite impairment of liver function after protracted surgical operations, even when the operative site is such that mechanical trauma to the liver is ruled out.

The changes in liver function are probably significant in that they may represent one of the factors contributing to the complex syndrome called "post-

operative disease." The prevention and control of these changes deserve further study

### SUMMARY

There was a significant increase in the retention of bromsulfalein immediately after an extra-abdominal operation in 14 of 20 patients studied. No similar changes were observed in the thymol-turbidity and cephalin-flocculation tests.

There was a certain degree of correlation between the severity of the operation and the postoperative appearance of an impaired ability of the liver to clear the blood of bromsulfalein. Other factors, such as anesthesia by ether or pentothal sodium and the age of the patients, appeared less important. The significance of these facts in relation to the physiologic changes brought about by a surgical operation is discussed.

We are indebted to Dr. Hayes Martin and Dr. Frank E. Adair for permission to study their patients.

## THE PROBLEM OF SULFONAMIDE-RESISTANT HEMOLYTIC STREPTOCOCCI\*

THOMAS L. HARTMAN, M.D.,† AND LOUIS WEINSTEIN, M.D.‡

BOSTON

PREVIOUS reports have discussed the problem and circumstances of the development of sulfadiazine-resistant hemolytic streptococci in the armed forces of the United States during 1944.<sup>1-8</sup> In a civilian community the occurrence of infections due to sulfonamide-resistant hemolytic streptococci<sup>9</sup> indicates that these organisms have had a wide distribution throughout the general population via military personnel. The possibility that these resistant organisms might become an epidemiologic and therapeutic problem in civilian life cannot be dismissed on the basis of the available information. Also, the likelihood of such a situation arising in the general population—that is, the development of sulfonamide-resistant or penicillin-resistant strains of hemolytic streptococci under the common therapeutic and prophylactic regimens—should be considered, and efforts directed toward its prevention.

A study of the sulfonamide sensitivity of hemolytic streptococci in the general population would indicate the prevalence of known sulfonamide-resistant strains and also whether there are naturally resistant strains that might assume increased resistance under proper circumstances. It is the purpose of this paper to present the results of sulfonamide-

sensitivity determinations of hemolytic streptococci as they occurred in a New England population, as well as an analysis of the available information pertaining to the conditions under which sulfonamide-resistant hemolytic streptococci developed.

### METHODS

The cultures studied were obtained from patients admitted to the Evans Memorial and Haynes Memorial Hospitals, serving Boston and the suburban areas surrounding it, during the fall and winter of 1946-1947. These patients were admitted to the hospital because they had clinical evidence of a streptococcal infection or were admitted for observation or study and found to harbor hemolytic streptococci. Most of the strains of hemolytic streptococci were isolated from the nasopharynx of patients who had clinical scarlet fever, others were obtained from streptococcal carriers or patients with pharyngitis, otitis media, pneumonia or wound infections due to the hemolytic streptococcus.

Cultures were obtained by swabbing of the nasopharynx or infected areas with culture swabs. The swabs were wiped on 2 per cent blood-agar plates, streaked and incubated aerobically at 37°C for twenty-four hours. Single colonies of beta-hemolytic streptococci were picked and transferred to blood-agar plates or to broth for further identification and study. The hemolytic streptococci isolated were grouped and typed by the precipitin technique,<sup>10</sup> antiserums for Types 1 to 47 were available. The

sulfonamide sensitivity was determined by the method of Wilson,<sup>11</sup> horse serum being used, susceptible and resistant strains were always run as controls. Only organisms growing in a concentration of 5 mg per 100 cc of sodium sulfadiazine were considered to be resistant. Occasionally scant growth appeared in the tube containing a concentration of 1 mg per 100 cc; however, owing to the conditions of this test, growth in this tube was not considered evidence of resistance.<sup>11, 12</sup>

### RESULTS

One hundred and sixty-seven Group A hemolytic streptococcus strains isolated during the fall and winter of 1946-1947 were tested for sensitivity to the action of sulfadiazine. The type distribution and sulfonamide sensitivity are indicated in Table 1. Types 18, 30 and 31 were the most prevalent, however, there was no predominant epidemic-type strain prevalent in this area. Types 1, 17 and 19, which were the predominant types in the Navy,<sup>1, 2</sup> did not assume any epidemic prominence in this study.

Of 167 strains of Group A hemolytic streptococci tested for sensitivity to the action of sulfadiazine, 166 were sensitive to its action—that is, none grew in a concentration of sodium sulfadiazine as great as 5 mg per 100 cc. One strain, a Group A, Type 19 hemolytic streptococcus, was resistant to the action of sodium sulfadiazine in a concentration of 25 mg per 100 cc. This sulfonamide-resistant strain was isolated from a patient who had clinical scarlet fever and later developed electrocardiographic and clinical evidence of rheumatic heart disease. This strain was sensitive to 0.0078 units of penicillin, as determined by the method of Rammelkamp.<sup>13</sup>

### DISCUSSION

Recent publications have offered some suggestions regarding the possible origin of sulfonamide-resistant streptococci.<sup>3, 4, 9, 12, 14, 15</sup> From theoretical points of view these resistant bacteria could exist as naturally occurring variants, they could arise as variants of normally susceptible strains as a result of contact with and adaptation to the drug, or they could arise as spontaneous genetic mutants. Whatever the explanation of this phenomenon, once sulfonamide-resistant variants appear they increase in prevalence in a sulfonamide-containing environment as a result of their greater fitness to survive. It is of interest to determine what light recent clinical and epidemiologic experience has shed on this problem.

Although methods to detect the development of sulfonamide resistance by other bacteria in vitro were known, attempts to demonstrate the resistance of hemolytic streptococci to sulfonamides, by the use of ordinary mediums containing sulfonamide inhibitors, were uniformly unsuccessful.<sup>3</sup> The need for a method of demonstrating sulfonamide re-

sistance in vitro became urgent with the failure of the mass chemoprophylaxis program in the armed forces in 1944. During that year Wilson<sup>11</sup> developed a technic that enabled one to determine the ability of hemolytic streptococci to grow in a semisolid medium free of sulfonamide inhibitor and containing respectively 0, 1, 5, 25 and 125 mg per 100 cc of sodium sulfadiazine. This test conclusively demonstrated the presence of sulfonamide-resistant strains of hemolytic streptococci, which were the cause of increasing numbers of upper respiratory infections while sulfonamide prophylaxis was being carried out in the armed forces.<sup>2, 4</sup>

After the first demonstration of sulfonamide-resistant Types 3, 17 and 19 Group A hemolytic streptococci during a program of mass chemopro-

phylaxis in the armed forces,<sup>2, 4</sup> it became essential to know if there were any resistant strains before this program was inaugurated in the Navy in December, 1943.<sup>1, 2</sup> This information could be obtained only by tests of cultures that had been preserved prior to this program of mass chemoprophylaxis. No sulfonamide resistance was demonstrated in over 100 of the strains of hemolytic streptococci preserved at the Rockefeller Institute Hospital prior to 1937.<sup>19</sup> Siegel<sup>17</sup> showed that 90 strains of Group A hemolytic streptococci isolated from scarlet-fever patients before 1938 were sensitive to the action of sulfadiazine. Sensitivity determinations on strains of hemolytic streptococci isolated from patients with scarlet fever<sup>12</sup> in the United States Navy prior to December, 1943, did not show any evidence of resistance. Most of these strains were Type 19, and some were isolated from patients who had been receiving small doses of sulfadiazine during a scarlet-fever epidemic in New York City.<sup>19</sup> It should be noted that strains of Type 19 later

appearing in the armed forces were resistant to sulfonamides. From this information it seems safe to conclude that before the program of mass sulfadiazine prophylaxis had been initiated in the armed forces in 1943 there were no known sulfonamide-resistant Group A hemolytic streptococci.

Rantz et al,<sup>14</sup> however, reported the results of testing strains of Group A hemolytic streptococci isolated in the Army from December, 1943, to April, 1944, and observed that some of the typed strains were more resistant than others—that is, that they grew in suspensions of 1 mg and 5 mg of sodium sulfadiazine per 100 cc. The authors were of the opinion that these strains were naturally resistant to moderate amounts of sulfadiazine and were the precursors of the more highly resistant strains such as Types 3 and 17, which later became established as epidemic, resistant strains. The possibility of transfer of these resistant strains to Army personnel by members of the Navy on chemoprophylaxis cannot be ruled out.

Several studies of streptococcal carriers treated with sulfadiazine to rid them of the carrier state are enlightening in demonstrating the possibility of the development of resistance under those conditions of treatment. Strains of hemolytic streptococci isolated from 40 patients before and after treatment with therapeutic doses of sulfadiazine did not show any evidence of the development of resistance to sulfadiazine.<sup>12</sup> Another study of 10 carriers treated with 1 gm of sulfadiazine daily for a ten-week period did not reveal any increase in sulfadiazine resistance of the post-treatment cultures as compared with the pretreatment strains.<sup>17</sup> Hamburger et al<sup>19</sup> treated 45 carriers of Group A hemolytic streptococci with 1 gm of sulfadiazine daily for four-day to fifty-day periods, with no development of sulfadiazine-resistant strains during the treatment period. So far as is known at present, no evidence of the development of resistant strains of hemolytic streptococci has been reported from any rheumatic fever patients who are receiving daily prophylactic treatment with sulfonamides.<sup>20</sup> Under the conditions of the studies cited above, no resistant strains of hemolytic streptococci developed.

The spread and epidemiologic problems that these resistant organisms presented in the armed forces have been summarized in previous reports<sup>3-8, 16</sup>. Although it was known that the civilian population was exposed to these resistant strains of hemolytic streptococci, no epidemics therefrom were reported until 1946, when an outbreak of Type 19 infections appeared in Cooperstown, New York.<sup>9</sup> Except for the Type 19 strains, resistant to 25 mg per 100 cc of sodium sulfadiazine, isolated during that study, none of the types showed any evidence of resistance. In the present report all strains, except the one resistant Type 19 strain, were susceptible to the action of sodium sulfadiazine. Apparently, there have been no problems of therapy in these resistant

streptococcal infections since they can be adequately treated with penicillin.<sup>21</sup>

The results of the present study of 167 strains of Group A hemolytic streptococci indicate that only one strain, which belonged to Type 19, was resistant to the action of sulfadiazine. This strain grew in a concentration of 25 mg of sodium sulfadiazine per 100 cc—the same concentration as the epidemic Type 19 strains that were prevalent in the armed forces. The source of this strain is not known, but it was probably introduced into this area by Army or Navy personnel. The possibility that this resistant strain is a naturally resistant variant cannot be ruled out, but the available information indicates that the resistant organism encountered in this study was the same as that in the armed forces.

The data of this study show that sulfonamide-resistant variants of Group A hemolytic streptococci did not arise in this area of Boston and its environs, where sulfonamides are used in the customary manner in the treatment of patients and where sulfonamide prophylaxis has not been widely employed.

From the accumulated evidence presented, it seems that conditions of mass sulfadiazine prophylaxis as they existed in the armed forces<sup>1, 2</sup> were conducive to the development of sulfadiazine-resistant strains of hemolytic streptococci. Regarding the conditions under which drug-resistant organisms can be expected to arise, one observer has postulated that “the infection shall be a common type providing very large numbers of micro-organisms within which a rare mutation has a chance to arise, and second—and this is the medically important point—that a large proportion of the potential hosts shall be treated with the drug in question.”<sup>16</sup> To date these resistant strains have not presented any particular problem in civilian life and can be adequately treated by penicillin therapy. The possibility of the development of resistant strains of bacteria during large-scale mass prophylactic programs should be kept in mind, and such programs should be used only as an emergency measure.

## SUMMARY

Sulfonamide sensitivity determinations on 167 strains of Group A hemolytic streptococci, isolated from patients from Boston and surrounding suburbs, are presented. Only one strain, Type 19, was resistant to 25 mg per 100 cc of sodium sulfadiazine.

The pertinent literature regarding the development of sulfonamide-resistant hemolytic streptococci is reviewed.

## MEDICAL PROGRESS

### THE ROLE OF PLEUROPNEUMONIA-LIKE ORGANISMS IN GENITOURINARY AND JOINT DISEASES (Concluded)\*

LOUIS DIENES, M.D.,† MARIAN W. ROPEL, M.D.,‡ WILLIAM E. SMITH, M.D.,§ SARABELLE MADOFF AND WALTER BAUER, M.D.¶

BOSTON

THE high incidence of acute joint disease in male patients with positive prostatic cultures, in addition to the knowledge that animals infected with L organisms frequently have arthritis, suggests that pleuropneumonia-like organisms play a role in producing the joint disease in the patients. The hypothesis that this organism is the cause of the arthritis is somewhat supported by the fact that in 2 cases of Reiter's syndrome (as Case II) L organisms were cultured from the knee-joint fluid. However, no L organisms were found in the synovial fluids in the other 11 cases in this series in which a search for these organisms was made.

In women, a relation between the presence of the L organism in the genital tract and the development of joint disease was not so apparent. Among 58 women yielding positive cultures in the original series, only 9 had joint complaints. One of these patients also had gonococci in the cervical cultures. Two other cases were arbitrarily introduced into the series since they had rheumatoid arthritis and formed part of a group of 12 female patients with

rheumatoid arthritis in whom routine examination of cervical cultures for L organisms was made. Five of the 6 remaining patients had had swelling and pain of long duration in various joints. The other patient (Case 10) had an acute arthritis that had developed two weeks after marriage. Her husband (Case 9) also developed joint symptoms eight weeks after marriage, and L organisms were found in the prostate at that time. In view of the high incidence of L organisms in the female genital tract (26 per cent) and the relatively low percentage of joint disease in female patients with positive cultures, there is no definite evidence of a relation between the L organism and the joint disease in these cases. However, the observations in the married couple suggest not only that the joint involvement was related to the L organism but also that certain strains have a greater tendency than others to produce joint disease. Further suggestion of a possible relation between the L organism and joint disease in women was furnished by 2 other patients, seen since the original series was completed, who had acute arthritis at the time cervical cultures were positive for L organisms and negative for gonococci.

Until further information is available concerning the pathogenicity of the various human strains of pleuropneumonia-like organisms, it is difficult to conclude whether or not the conditions produced by these organisms are contagious. Certain findings suggest that they are. The wives of 5 of the men from whose prostates L organisms were cultured

¶Associate professor of medicine, Harvard Medical School; physician, Massachusetts General Hospital.

were studied, and in 2 cases *L* organisms were found in the cervical cultures. In 1 case—that of the married couple discussed above—both husband and wife developed acute arthritis soon after marriage. Beveridge, Campbell and Lind<sup>9</sup> cultured pleuropneumonia-like organisms from 3 of 11 women from whom men had contracted nonspecific urethritis. The fact that the genitourinary, joint or eye symptoms in at least 7 of the men with positive cultures in the present series developed within a few days after sexual exposure suggests that the disease is venereal in some cases. However, in many cases no history of exposure was obtained. The possibility that the gastrointestinal tract was the portal of entry in some cases is suggested by the fact that at least 6 patients had diarrhea just before or at the onset of the disease.

The treatment of diseases produced by pleuropneumonia-like organisms is still in an experimental stage. In rats and mice these diseases have been shown to be prevented or effectively treated in a high percentage of cases by gold compounds<sup>22, 23</sup> and by streptomycin.<sup>24</sup> Penicillin has not been effective in animals.<sup>25</sup> Pleuropneumonia-like organisms are not sensitive *in vitro* to sulfonamides or penicillin, but the growth of some strains has been found to be inhibited by streptomycin in a concentration of 20 microgm per cubic centimeter.<sup>17</sup> In the present series gold was used in only 1 patient (Case 4) and was ineffective. None of the patients treated with sulfonamides or penicillin showed any improvement in the genitourinary or joint symptoms. Streptomycin was used in 8 patients in whom the infection was limited to the genitourinary tract (see Cases 4 and 5), including 4 cases of cystitis, in 1 patient with acute arthritis associated with urethritis, and in 5 patients with Reiter's syndrome (Case 12).<sup>\*</sup> In 7 of the 8 cases of genitourinary-tract infection there was rapid disappearance of symptoms during treatment, and cultures became negative for *L* organisms. The eighth case, in a patient who had had urethritis for sixteen years (Case 4), showed only a transient improvement in symptoms, and the pleuropneumonia-like organisms did not disappear from the urethral cultures. In the patients with acute arthritis or Reiter's syndrome, there was improvement in symptoms during and immediately after treatment. However, evidence of joint inflammation persisted for weeks, and the sedimentation rates remained elevated. In none of the cases were *L* organisms cultured after treatment. Streptomycin therapy did not prevent recurrences of the disease in Case 12. The results of streptomycin therapy were not conclusive but indicate that the drug is probably effective in most cases of uncomplicated genitourinary-tract disease due to pleuropneumonia-like organisms. In Reiter's

syndrome the results were sufficiently suggestive to warrant further trial of this therapy.

### CASE REPORTS

The following brief abstracts include characteristic cases from the various groups.

**CASE 1 (M G H 22349) †** A 33-year-old female research worker who handled rats almost daily and who gave no history of previous genitourinary disease noted sudden onset of tenderness and swelling of the right labium majus 10 days after marriage. On examination an abscess of Bartholin's gland was found. Cervical smears were negative for gonococci. Excision of the abscess *in toto* was performed, and cultures were made at the operating table from the center of the abscess, which contained creamy-yellow pus. These cultures yielded an abundant growth of *L* organisms in pure culture. Streptobacilli or gonococci could not be demonstrated by smear or culture. The patient recovered uneventfully.

**CASE 2** An 18-year-old single girl noted the onset of profuse vaginal discharge 4 days after intercourse. On examination there was an acute vaginitis, with a fiery-red mucosa and yellow purulent exudate. Cultures of this exudate yielded a pure growth of *L* organisms. Gonococci could not be demonstrated by smear or culture. The vaginitis cleared up within 1 week.

### Patients with Urethritis and Prostatitis

**CASE 3** A young married man, 36 hours after extramarital exposure, observed slight urethral discharge. On examination no discharge was apparent, but the prostate was found to be swollen and painful. In the culture made from a sample of urine immediately after prostatic massage many *L* colonies but no gonococci were seen. A second culture 10 days later was negative for *L* organisms and for gonococci. The subsequent clinical course is not known.<sup>‡</sup>

**CASE 4 (M G H 492207)** A 35-year-old married man was admitted to the hospital because of persistent urethral discharge. Sixteen years previously, 3 days after intercourse, he had developed a yellowish urethral discharge and in ginal lymphadenopathy. The discharge had not changed throughout the 16 years despite many types of treatment, including sulfonamides, penicillin and numerous kinds of local therapy. Cultures had always been negative for gonococci, but during the year before admission had been positive for pleuropneumonia-like organisms on several occasions. Examination was negative except for slight urethral discharge and enlargement of the prostate. The patient was treated with streptomycin, in a dosage of 4 gm a day, for 1 week. The discharge disappeared after 1 day of treatment, but cultures of the prostatic secretion continued to show many colonies of *L* organisms. Ten days after treatment was stopped the discharge returned and has persisted for the past 11 months. During this interval he has been treated with myocresine, receiving 325 mg in 5 weeks without effect.

### Patients with Cystitis

**CASE 5 (M G H 532255) §** A 26-year-old single man was admitted to the hospital because of frequency of urination and terminal hematuria. Three years before admission he had had urethral discharge and frequency of urination lasting for several weeks. Subsequently, there had been repeated recurrences of burning and frequency. Two weeks before admission he had first noted blood in the terminal portion of the urine. Cultures had always been negative for gonococci. Examination was negative except for the fact that the prostate was rather soft. The urine was loaded

\*We are indebted to the Committee on Chemotherapeutics of the National Research Council for the streptomycin used during most of this study and to Merck and Company for the streptomycin now being employed for test of its efficacy in the treatment of infections due to pleuropneumonia-like organisms.

†We are indebted to Dr. L. Parsons, of the Massachusetts General Hospital for permission to report this case. Reference to this patient has been made by Dienes and Edsall.<sup>12</sup>

‡This was a patient of the late Dr. Richard F. O'Neil.

§We are indebted to Dr. Fletcher H. Colby, of the Massachusetts General Hospital, for permission to include this case which has also been reported by Kane and Foley.<sup>11</sup>

with erythrocytes and leukocytes. Three routine cultures of urine showed no growth, but cultures on hotted blood ascitic agar contained numerous colonies of pleuropneumonia-like organisms. The patient was given 2 gm of streptomycin daily for 4 days and 1 gm daily for the following 5 days. Cultures became negative for L organisms after 3 days of treatment, and the urinary sediment showed only rare cells. There has been no recurrence of symptoms in the subsequent 14 months.

### *Patients with Chronic Arthritis*

**CASE 6 (M. G. H. 534532).** A 32-year-old married man was admitted to the hospital because of severe pain and redness of the right eye of 1 week's duration. Seven years before admission he had had a urethral discharge, smears from which were reported to contain gonococci. Five years later he had begun to notice migratory pains in the hips, right knee, neck and lower back. Six months before admission the right knee became swollen and painful. Examination showed an iritis of the right eye with marked ciliary injection, an effusion in the right knee and slight tenderness and induration of the prostate. Prostatic cultures showed a moderate growth of L organisms and of non-hemolytic streptococci. The arthritis subsided in 3 months but the iritis still persists at the end of 11 months. During this period central chorioiditis has developed and has been treated with fever induced by intravenous injection of typhoid vaccine. Prostatic cultures have remained positive for L organisms.

It is impossible to determine whether or not the various features of this patient's disease are interrelated in any way.

### *Patients with Acute Arthritis without Eye Involvement*

**CASE 7 (M. G. H. 352561).** A 47-year-old married man noted burning on urination 2 or 3 days after sexual exposure. One week later he developed stiffness of the knees, right wrist and right shoulder. The stiffness of the knees persisted, and 3 weeks later the left wrist became very swollen, red, hot and tender. These symptoms subsided in 2 or 3 days but the right wrist became involved. Examination on the following day showed tenderness, increased heat and pitting edema of the right wrist and the dorsum of the right hand and a moderate-sized effusion in the left knee, which was warm and tender. The prostate was tender and boggy. Culture of the prostatic secretion showed numerous colonies of L organisms and *Staphylococcus aureus*; but was negative for gonococci. All symptoms subsided in 2 weeks though the sedimentation rate remained elevated. There was no recurrence of symptoms during the subsequent 2 years.

**CASE 8 (M. G. H. 315068).** A 29-year-old single man had had a urethral discharge 6 months before admission. Soon thereafter he had noted pain and swelling of the left knee, left third toe and right third finger. There had been no response to sulfonamide therapy but the symptoms subsided slowly over the course of 4 months. Two weeks before admission the urethral discharge recurred and pain developed in the right hip, left shoulder and tarsometatarsal joints on both sides. The patient had had a urethritis said to be of gonococcal origin, 8 years before admission. On examination at the time of admission the left knee contained a moderate-sized effusion and was tender. The prostate was large and boggy. Cultures of prostatic secretion showed abundant L colonies but no gonococci. The patient was again treated with sulfonamides with no effect. The symptoms gradually disappeared over the course of 2 months. Cultures of prostatic secretion were negative for L organisms 4 years later.

**CASE 9 (M. G. H. 291517).** This 38-year-old man the husband of the patient in Case 10, was seen in 1942 when he had been married 8 weeks. He had had urethritis in 1929 and again in 1934. Gonococci were said to have been seen in smears during both these attacks, but they could never be demonstrated at any time thereafter. In 1937, 1940 and 1941 he had been treated for chronic prostatitis, smears showing pus cells but no gonococci. In March 1942, the patient was admitted to the hospital for painful swelling of the left wrist of 3 days' duration. On examination the prostate did not feel abnormal but massage yielded fluid containing 20 to

30 pus cells per high power field. Cultures yielded no gonococci but gave an abundant growth of L organisms, streptococci and diphtheroids. Four months later pain and swelling developed in the right elbow, persisting for 9 months. During this episode the prostate was found to be boggy and the vesicles were tender. Prostatic cultures yielded occasional L organisms and an abundant growth of hacteroides, nonhemolytic streptococci and *Staph. albus*. Four years later the patient had recurrent attacks of pain in the left flank and x-ray study showed a stone in the lower end of the left ureter. At the time of admission for removal of the stone the urine was cultured but showed no growth of pleuropneumonia-like or other organisms.

**CASE 10 (M. G. H. 348216).** A 30-year-old woman, the wife of the patient in Case 9, was admitted to the hospital in March, 1942, 3 days after her husband's first admission. She gave no history of genitourinary disease and had been well until 6 weeks before entry, when 2 weeks after marriage she developed stiff, swollen knees. There was no redness or heat about the knees and the swelling caused only moderate discomfort. No other joints were involved and there was no fever and no constitutional symptoms. Pelvic examination revealed a slight cervical discharge, cultures of which yielded a pure growth of L organisms. No organisms were found in gram stained or Giemsa stained films of the joint fluid and none could be recovered in culture. The patient was discharged unimproved after 1 week. The involvement of the knees gradually subsided during the following year.

### *Patients with Acute Arthritis with Eye Involvement (Reiter's Syndrome)*

**CASE 11 (M. G. H. 440804)\*.** A 26-year-old single man developed a purulent urethral discharge 36 hours after sexual exposure. He was treated with sulfathiazole and sulfadiazine, but the discharge persisted and 3 weeks after onset he noted burning, frequency, urgency and terminal hematuria. Approximately 5 weeks later bilateral conjunctivitis appeared and within a few days he complained of pain in the lumbosacral region, as well as pain and swelling of the right ankle, right shoulder, left elbow and left knee. On examination 3 days later, the temperature was 100.4 F. with slight conjunctival injection and swelling and tenderness of the right ankle, left knee and right sternoclavicular joint. The urethral discharge had subsided but a catheterized specimen of urine was loaded with white cells. Cultures of the urine and prostatic secretion showed an abundant growth of L organisms and a few colonies of staphylococci but were negative for gonococci. Two colonies of L organisms were found in the culture of fluid from the left knee. At the time of discharge, cultures of the urine showed only a few L organisms. The patient was treated with 120,000 units of penicillin without effect but all symptoms subsided slowly during the course of 2 months.

**CASE 12 (M. G. H. 255127).** A 26-year-old single man had had pain in the right ankle and right knee and slight urethral discharge for 2½ weeks before admission. Examination revealed marked swelling of the right knee with an effusion and moderate swelling of the right ankle. The prostate was slightly enlarged and boggy. Three weeks later an iritis developed in the left eye. Culture of the prostatic secretion showed abundant growth of L organisms and many streptococci and colon bacilli but was negative for gonococci. The patient was treated with sulfathiazole and penicillin without effect. The symptoms gradually subsided during the course of 6 months. He had had a similar attack 4 years previously with bilateral conjunctivitis and keratitis, purulent urethral discharge and arthritis. There had been a second attack 1 year later manifested by urethral discharge, balanitis and prostatitis, bilateral conjunctivitis and keratitis and arthritis.

After the third attack described above had subsided the patient remained entirely well except for occasional episodes of slight conjunctivitis until 1 year after discharge, when prostatic massage was performed. Culture of the prostatic

\*We are indebted to D. Fletcher H. Colby of the Massachusetts General Hospital, for permission to report this case, the penitentiary features of which have been reported by him.<sup>10</sup>

†These first two attacks have been reported elsewhere.<sup>11</sup>

secretion was negative for L organisms. Two days later, he noted slight urethral discharge and 1 week later developed bilateral conjunctivitis. During the following week, the right hip and both knees became painful. On examination the conjunctivas of both eyes were markedly inflamed. The right hip was painful, and both knees contained effusions. Prostatic cultures showed an abundant growth of L organisms and a few staphylococci but no gonococci. The urethritis and conjunctivitis subsided in 2 weeks, but during the following 2 months, he continued to have intermittent attacks of pain, swelling and tenderness of wrists, knees and left first metacarpophalangeal joint. Roentgenograms showed moderate decalcification of the bones around the knees and wrists. At the end of 2 months, streptomycin was obtained, and the patient received 21.5 gm in 6 days. Subsequently, he had no further recurrence of joint symptoms though the sedimentation rate remained slightly elevated for 3 months.

Thereafter, he continued to feel well until 3 months later, when he noted stiffness and swelling of the left knee. Four days later there was recurrence of slight urethral discharge and on the following day slight conjunctivitis. On examination 5 days later, the left knee and the interphalangeal joint of the right first toe were hot, red, very painful and swollen. There was a severe conjunctivitis, with purulent discharge, and a slight urethral discharge. Cultures of the urethral discharge and of the urine showed a moderate growth of L organisms and a few colon bacilli and *Staph. albus* and *Staph. aureus*. Roentgenograms showed persistence of slight decalcification of the bones around the knees. The patient was treated with streptomycin in a dosage of 4 gm a day for 13 days. The urethritis and conjunctivitis subsided within 1 week, but swelling of the left knee persisted for 2 months. The sedimentation rate has remained slightly elevated for the past 5 months.

### DISCUSSION

The observation that human beings may harbor organisms belonging to a group that includes several important animal pathogens is in itself interesting. Interest is heightened by the fact that these pleuropneumonia-like organisms appear to be pathogenic to human beings. The most definite indication of pathogenicity has been obtained from the study of male patients. The fact that all the patients in this series had urethritis, prostatitis or cystitis suggests that the organism is pathogenic for the genitourinary tract. Most impressive were the patients with cystitis, such as Case 11, in whom the L organisms were present in pure culture for a long period and decreased markedly or disappeared from the urine as the clinical symptoms subsided. Further indication of the pathogenicity was obtained from one of the patients with Reiter's syndrome (Case 12). L organisms were cultured from the prostatic secretion at the onset of three separate attacks of the disease and were not found in the interval between the episodes.

The presence of acute joint involvement in 27 of the 58 men with positive cultures for L organisms suggests pathogenicity for synovial tissues as well as the genitourinary tract. In 2 patients with Reiter's syndrome, organisms were cultured from the synovial fluid. This association with joint disease is of particular interest because joint involvement is a common feature of the diseases produced by the pleuropneumonia group of organisms in animals.

The evidence of pathogenicity gained from the study of female patients is more equivocal. The relatively high incidence of L organisms in the

female genitourinary tract suggests that they are part of the normal bacterial flora in this location. On the other hand, their presence in various inflammatory processes of the genitourinary tract either in pure culture or in much greater abundance than other bacteria suggests that they are at times pathogenic.

In evaluation of the evidence gathered to date it should be remembered that some strains are presumably not recovered by the present methods, and that the strains isolated probably belong to more than one species and differ in their pathological significance. The fundamental biologic study of the organism obtained from human beings is still in a primitive stage. The cultural methods, which at present are the only means of recognition, are probably inadequate. Attempts are now being made to develop biologic methods, such as serologic and skin tests. The need for a more detailed study of the properties of the various strains, especially their serologic characteristics and their pathogenicity, is indicated by the observations that attest to their ability to cause disease in human beings.

Further difficulty in evaluating the role of pleuropneumonia-like organisms arises from the fact that some of the bacteria commonly found in human beings grow in an L variant form under certain cultural conditions, as in the presence of penicillin. Because of this difficulty, the 8 male patients with severe urinary-tract infection in whom L organisms were found only after the growth of other bacteria was suppressed either by addition of penicillin to the medium or by treatment of the patient with penicillin or streptomycin have not been included in the present series. It is impossible to assess the significance of the L organisms in these cases. It seems probable that they represent one of the many organisms that together cause the urinary-tract infection. However, they may be variant forms of the other bacteria present in the inflamed urinary tract.

### SUMMARY

The properties of pleuropneumonia-like organisms (L organisms) and the methods used for their isolation and identification are briefly described.

Pleuropneumonia-like organisms were present in 58 of 222 routine specimens (26 per cent) from the uterine cervix and vagina and may be part of the normal bacterial flora in these locations. Suggestion of possible pathogenicity, however, was provided by their recovery from inflammatory processes of the female genital tract.

Pleuropneumonia-like organisms were found in only 6 of 71 routine specimens from the male genitourinary tract. Evidence of their pathogenicity was more definite than that in women, since all 58 patients of this series from whom positive cultures were obtained had urethritis, prostatitis or cystitis. In 6 of the 9 cases in which the

infection extended into the bladder the organisms were obtained in pure culture from the urine. Gonococci and L. organisms were found simultaneously in only 2 male patients.

Material from other sources, including the respiratory and gastrointestinal tracts and cerebrospinal fluid, was examined by similar methods but with negative results except in synovial fluids from 2 patients with Reiter's syndrome.

Eighteen of the 58 male patients with genitourinary-tract infections had an acute type of arthritis when the cultures were positive for L. organisms. Nine of these men had simultaneous urethritis, conjunctivitis and arthritis, the syndrome characteristic of so-called Reiter's disease. In 1 patient L. organisms were found in the prostate during three attacks of the disease.

These observations indicate that pleuropneumonia-like organisms have pathogenic activity in the genitourinary tracts of men and women and may be related etiologically to an acute infectious type of arthritis and to Reiter's syndrome.

We are indebted to the following physicians for permission to include cases in this series: Drs F. Albright, J. D. Barney

W. W. Beckman, R. Chute, F. H. Colby, L. W. Kane, S. B. Kelley, S. McGinn, L. S. McKinnick, J. V. Meigs, L. Parsons, C. L. Short and H. T. Suby of the Massachusetts General Hospital; Dr R. L. Berg of the United States Naval Hospital, Chelsea; Drs T. H. Flynn and A. H. Mayby of the United States Marine Hospital, Brighton; Dr J. A. McLaughlin, Naval Air Station, Squantum; Dr T. A. Warthin, Veterans Administration Hospital, West Roxbury; and Cushing Veterans Administration Hospital, Framingham.

Eight of the cases of this series have been included in other papers:<sup>11, 12, 13</sup> Seven others will be reported by Berg and McLaughlin.

BENJAMIN CASTLEMAN, M.D., Associate Editor

EDITH E. PARRIS, Assistant Editor

### CASE 34161

#### PRESENTATION OF CASE

A three-and-a-half-month-old male infant entered the hospital because of persistent diarrhea.

The birth weight was 6 pounds, 3 ounces, and a statement was made that the baby was blue at birth. However, he gained weight at a normal rate, ate well, and seemed normal in every way except that when he cried or breathed rapidly some cyanosis appeared. There had never been any convulsions, hematuria, vomiting or jaundice.

Four weeks prior to entry the patient developed a cough and coryza, and had several bouts of what were said to be projectile vomiting. Four days later he was taken to another hospital, where a diagnosis of bronchopneumonia was made. X-ray films at that time showed the heart to be to the right of the sternum and an additional diagnosis of congenital heart disease was made. He remained in the hospital and ten days before admission to this hospital

he developed a persistent and moderately severe diarrhea (ten to twelve bowel movements per day). Several of the other infants on this ward also developed diarrhea at about the same time. Five days before admission the diarrhea became much severer, and penicillin therapy was started. Because of the persistent diarrhea the patient was transferred to this hospital.

Physical examination revealed a marasmic and cyanotic infant. He appeared to be fairly well hydrated. Cyanosis was present to a mild degree but was considerably intensified when the patient cried. The chest was clear to percussion and auscultation. The heart was percussed to the right of the sternum and the point of maximum impulse was in the fifth interspace 4 cm. to the right of the sternum. The rhythm was normal, and the rate was 140. There was a soft, Grade II systolic murmur heard best in the third interspace to the left of the sternum.

Examination of the blood disclosed a red-cell count of 4,740,000, with a hemoglobin of 14 gm., and a white-cell count of 7500, with 88 per cent neutrophils. The urine was normal. Blood cultures were negative, and cultures of the stool showed no significant organisms. A blood Hinton test was negative. A tuberculin test in a dilution of 1:1000 was negative.

Soon after admission the number of daily bowel movements decreased markedly, until they became normal. On the third hospital day the child had an episode of severe cyanosis associated with vigorous respiratory activity. The trachea was suctioned, and much thick white mucus was recovered. The patient recovered entirely within fifteen minutes.

The next day a swallow of lipiodol was given, and x-ray examinations showed no evidence of an esophagotracheal communication. The lipiodol passed down the esophagus into the stomach, which lay in normal position on the left side. There was no evidence of constriction of the esophagus. There was a slight indentation opposite the arch of the aorta, which seemed to indicate that the aorta descended on the left side. There was also a ques-

dural taps were done on the eighth day, without return of fluid. On the fourteenth day the temperature began to spike up to 102°F. The white-cell count was 10,900. Physical examination showed a questionable decrease in the percussion note over the left lower lobe. Because he was not taking his feedings very well, the patient had been started on stomach-tube feedings. On the twentieth hospital day, immediately after one feeding, he began to cough, became cyanotic, breathed very rapidly, and died, despite attempts at suction and artificial respiration.

#### DIFFERENTIAL DIAGNOSIS

DR FRANCIS McDONALD Will Dr Wyman please demonstrate the films?

DR STANLEY M. WYMAN The best demonstration of the esophagus is shown by the opaque tube, which extends through the esophagus into the stomach on the right side. The heart is seen on the right.

DR McDONALD "There was a slight indentation opposite the arch of the aorta, which seemed to indicate that the aorta descended on the left side."

DR WYMAN That is suggested on one of the spot films. However, a better look at the plain film with the tube in place shows a considerable shadow to the right of the esophagus and trachea, which makes me think that the aorta actually descends on the right side rather than on the left. I think that the observation of the left-sided aorta is perhaps inaccurate. The filling defect I cannot identify. There is good filling of the esophagus in this portion. I can detect no true abnormality from the films, which are not satisfactory and are noncontributory. The chest films show that the heart is in the right side of the chest, with the apex pointing to the right. The heart is not grossly enlarged. The pulmonary-vascular shadows are decreased in prominence. There is some multiple increased density in the left lung field medially. I should think that this was some sort of pneumonic process. It is seen on the other films consistently. We can therefore say that the heart is not grossly enlarged and lies on the right side (a dextroposed heart), the pulmonary vascular shadows are decreased in prominence and there is presumably some congenital anomaly.

DR RONALD C. SNIFFEN The liver is on the right side?

DR WYMAN Yes, it is on the correct side.

DR McDONALD Was the mucus removed by the bronchoscope cultured?

DR CHARLES U. LOWE It was cultured and yielded *Staphylococcus aureus*.

DR McDONALD I would welcome expert advice on the electrocardiogram.

DR SNIFFEN I do not believe there is anyone here who can give it.

DR McDONALD It sounds like a relatively clear-cut interpretation. About the only mistake that might be made is transposition of the arm electrodes.

FIGURE 1 Roentgenogram, Showing the Apex of the Heart in the Right Midclavicular Line

tionable filling defect just above the aortic arch as seen on the anteroposterior view. The lung fields were essentially clear, without evidence of active disease. The pulmonary vascular markings throughout seemed to be decreased. The apex of the heart lay in the right midclavicular line (Fig 1).

On the sixth hospital day the patient had a cyanotic episode, much the same as the previous one. However, suction did not relieve the attack, and a laryngoscope and then a bronchoscope were passed and a small amount of mucus was removed. After oxygen had been administered for some time the patient was able to breathe somewhat more easily, but there was still considerable forcefulness to the respiratory movements and some retraction of the interspaces. Because of the presence of bubbling rales at the lung bases sulfadiazine and penicillin therapy were instituted. An electrocardiogram was interpreted as being consistent with dextrocardia. The spinal fluid was not remarkable. Bilateral sub-

I am not a cardiac expert, so that for the interest of the group, I shall quote from Taussig's\* book.

Lead I is in the mirror image of normal. Leads II and III replace each other. In Lead I both P waves and the T waves are normally inverted and the principal deflection of the QRS complex is downward. The findings in Lead III are those usually seen in Lead II and the form of deflection in Lead II is similar to that seen normally in Lead III.

DR SNIFFEN The interpretation of the electrocardiogram was as follows: "The tracing is consistent with dextrocardia and inverted Lead I and interchanged electrodes 2 and 3 give normal axis and T waves."

I might say that the child did much better in an oxygen tent than is indicated in the record.

DR McDONALD It seems as if we have two main categories for diagnosis here. One is infection. We have an infant in an age group that is immunologically immature, subject to invasion by colon bacilli, staphylococci, influenza bacilli and other organisms, in addition to the usual streptococcal and pneumococcal invaders of the respiratory tract. It is extremely important in this age group to obtain blood cultures (using pour plates and broth flasks) and cultures of coughed-up secretions to obtain a precise idea what the organism is and to govern therapy accordingly. This patient was given sulfadiazine and penicillin, probably on that basis. *Staph aureus* was obtained on one attempt and cannot be passed off as a contaminating organism, as it frequently may in an adult group. *Staphylococcus* may be an invading agent in this age group. The cough, the dyspnea, the course and the x-ray findings, which might possibly be consistent with an early atelectasis or bronchiectasis as well as pneumonia, make me conclude that the baby did have pneumonia. The second diagnosis is a definitely proved cardiac abnormality. I believe that we can take the word of Dr Wyman that displacement of the heart was not likely from any of the physical findings or x-ray evidence. The electrocardiogram of dextrocardia is a conclusive finding. The presence of dextrocardia without situs inversus markedly increases the likelihood of associated anomalies. We can therefore assume that, in addition to the dextrocardia, either there were anomalies of the heart itself or, if by chance the aortic arch was on the left side, there was a good likelihood of anomalies of the vessels at the base of the heart. As may be seen in this case, the heart is twisted around, with the aortic arch where it should be normally, with the corresponding difficulty in readjustment of the vessels at the base. In addition to the diagnosis of dextrocardia without situs inversus I shall say question of pulmonary stenosis, question of single ventricle and question of anomaly of vessels at the base of the heart.

DR SNIFFEN You took care of this patient, Dr Lowe. Have you anything to add?

DR LOWE There are two things that might be clarified—first of all the difficulties with inspiration, the cyanosis usually followed feeding, which strongly suggested vascular anomaly at the base of the heart. The second point is that it was obvious that oxygen helped the child, which is unusual in children with cyanotic heart disease.

DR RICHARD SCHATZKI Is it not likely if a baby is short of breath that feeding usually makes the difficulty worse?

DR LOWE The child was not short of breath normally. The extreme attacks described in the record

FIGURE 2. Drawing of the Heart and Great Vessels Showing Persistent Truncus, Patent Interventricular Septum, Tricuspid Semilunar Valve, Pulmonary Arteries from Truncus, Persistent Fifth Aortic Arch on the Left and Right Sided Aorta.

occurred seven times while the child was in the hospital, and the last one was fatal. Dyspnea was not part of the general picture.

#### CLINICAL DIAGNOSES

Asphyxiation due to aspiration of feeding  
Persistent double aortic arch  
Dextrocardia  
Pneumonia  
Congenital heart disease

#### DR McDONALD'S DIAGNOSES

Pneumonia  
Dextrocardia  
? Single ventricle  
? Pulmonary stenosis  
? Anomaly of vessels at base of heart.

#### ANATOMICAL DIAGNOSES

Right-sided aorta  
Persistent truncus arteriosus  
Patent interventricular septum  
Persistent fifth aortic arch on left  
Acute purulent bronchitis with early bronchopneumonia

\*Taussig, H. B. *Congenital Malformations of the Heart*. 618 pp. New York: Commonwealth Fund, 1947.

## PATHOLOGICAL DISCUSSION

DR SNIFFEN At the time of death the patient was somewhat emaciated and cyanotic. The abnormal findings were confined to the heart and lungs. In the lungs there was a generalized purulent bronchitis most marked in the left lower lobe. This was accompanied by a mild peribronchial inflammatory infiltration involving the alveolar walls and septums. On the left side there was a fibrinous and fibrous pleurisy without effusion. A small amount of mucus and aspirated gastric contents were found in the trachea and major bronchi. The apex of the heart lay in the right midclavicular line. The pericardium and myocardium were normal,

arteries, which were not over 1 mm in diameter. The ductus arteriosus was not patent. Then, as one proceeded distally along the arch of the aorta, just beyond the left pulmonary vessel, an arterial trunk left the aorta. This trunk divided immediately into two branches, the first giving rise to the left subclavian and internal carotid arteries, and the second to the left external carotid artery. The next aortic branch was the right common carotid artery, with its external and internal divisions, and the last major vessel to leave the aortic arch was the right subclavian artery.

We believe that these structural abnormalities were the results of the disintegration of the first

FIGURE 3 Drawing, Showing Disintegration of the First Four Aortic Arches on the Left, with Persistence of the Fifth Aortic Arch

the latter measuring 4 mm in each ventricle. The heart was slightly enlarged.

The dissection of maldeveloped hearts is confusing, since minor structural variations change the interpretation of the developmental abnormalities a great deal. I shall demonstrate several diagrams so that I will not become snarled in the mechanics of the arterial abnormalities.

The first is a drawing of the heart and great vessels in this child (Fig 2). The heart showed a persistent truncus, and as might have been expected with this anomaly, there was a defect in the membranous septum between the ventricles. The truncus overlay both ventricular chambers, but mainly the right ventricle. The outlet was guarded by three normal semilunar valve cusps of equal size. The coronary vessels followed the usual course. There was a right-sided aorta. The first branches to arise from the truncus were two minute pulmonary

four aortic arches on the left side, with persistence of the fifth aortic arch (Fig 3). The reason for this opinion is the fact that the main trunk on the left side was very short. If it were long, we could be confident that the fourth arch had persisted after the disintegration of the first three arches. Furthermore, this main trunk arose immediately distal to the left pulmonary artery. On the right side the fourth arch and dorsal aorta had persisted to form the main arterial trunk.

The formation of three equal semilunar cusps in the truncus is difficult to understand. One would expect four cusps of equal size or unequal size or three unequal cusps. In fact the truncus had the structure of a normal aorta.

As a sidelight, the left lung was divided into three lobes, and the right lung had only two lobes.

No constrictions were found in the esophagus, and the abdominal organs were in the normal position.

## CASE 34162

## PRESENTATION OF CASE

A forty-eight-year-old chauffeur entered the hospital because of pain in the right elbow.

One year before entry the patient had a painful right upper arm for a few weeks following a strain in breaking a fall. He recovered completely from this episode, however, and remained asymptomatic until one month before entry, when he slipped and twisted the right arm while shoveling snow. He immediately sustained severe pain around the elbow, with radiation to the outer aspect of the right shoulder. The pain gradually subsided and disappeared a week later, when he first noted swelling of the "muscles" just above the elbow. Two weeks before entry physical examination and x-ray studies demonstrated a "tumor" of the lower humerus. One week later he slipped and fell and felt a crack in the arm, with resulting severe pain. X-ray films were taken, the arm was splinted, and he was sent to this hospital.

His father had died of carcinoma of the liver, and an uncle had carcinoma of the stomach.

The patient allegedly had enjoyed excellent health and denied weight loss, systemic symptoms, previous trauma or bone disease.

Physical examination revealed a well developed and well nourished man with moderate pitting edema below the lower third of the humerus, a swelling around the elbow and a soft-tissue mass, 2.5 by 5 cm., above the medial epicondyle, in the region of which there seemed to be some abnormal mobility. There was no discoloration of the skin and no evidence of motor or sensory impairment. A few firm, nontender lymph nodes (0.5 to 1.0 cm in diameter) were palpated bilaterally in the groin. No abdominal masses or chest abnormalities were demonstrated.

The temperature was 98°F, the pulse 76, and the respirations 15.

Examination of the blood showed a hemoglobin of 15.1 gm per 100 cc. and a white-cell count of 11,400, with 79 per cent neutrophils. Urinalysis was negative. No Bence-Jones protein was found.

X-ray films of the right humerus demonstrated a destructive process 10 cm long in the distal third through the entire thickness of bone but with no spicule formation, no new-bone formation, and no periosteal elevation, there was a pathologic fracture through this area. The medulla above the lesion had some irregular areas of mottling, and the cortex appeared roughened (Fig 1). Scout films of the chest, spine, pelvis, left arm and both legs were normal.

An operation was performed.

## DIFFERENTIAL DIAGNOSIS

DR CLIFFORD C FRANSEEN In the differential diagnosis of any suspected bone tumor, Dr Channing Simmons has taught us to review the history and

the signs and symptoms from three aspects: infectious, metabolic and neoplastic. The age (forty-eight years) is important to consider, as it is in any case of suspected bone tumor, and I shall deal with this later. This man either led a precarious existence or was very clumsy, because he suffered so many injuries from falls. Possibly, a neurologic examination would have thrown some light, but we do not have this information.

Let us consider infectious lesions first. With respect to osteomyelitis, the temperature was normal, and there was no suggestion of local inflammation. The record does not suggest a chronic inflam-

FIGURE 1

matory lesion, such as Brodie's abscess, especially by x-ray study. There was a slight elevation of the white-cell count, but little else to suggest that this process had arisen on the basis of osteomyelitis. In the latter lesions, also, enough reactive new-bone formation usually accompanies the osteomyelitis so that pathologic fracture is uncommon.

Syphilis must be considered only because it can simulate practically any bone lesion. The blood Hinton test is not given. We do not know whether or not it was taken, but, of course, it should be included in any study of a bone lesion. Syphilis, as a rule, produces considerable periosteal reaction, which was minimal or absent in this case. Tuberculosis can only be mentioned — we cannot rule it in or out in this case except for the statistical rarity of an isolated lesion in the humerus, especially since the chest film was normal.

We must consider the neoplastic group of diagnoses more seriously. The character of the destruction suggests that this was a neoplastic lesion, and probably a malignant one. Benign tumors that should first be considered are lesions such as bone cysts. They usually occur in the young age groups, and usually the first knowledge of their presence is the occurrence of pathologic fracture, unless they are picked up incidentally by an x-ray examination. It would be unusual for a man of this age to have one. A giant-cell tumor may remotely be suggested by the x-ray film, but the site in the bone is not a usual one. Perhaps we should see the x-ray films, since their interpretation becomes more important from now on.

DR STANLEY M. WYMAN: The lesion described lies in the lower third of the humerus (Fig. 1) but does not extend down to the condyles. It seems to be a purely destructive process. There is no visible new-bone formation and no evidence of periosteal reaction. The roughening of the cortex is seen on either side of the shaft, much higher on the humerus. The spine, both femurs and the bones of the pelvis and lumbar spine show no definite disease. The lung fields are clear, the heart is not remarkable. I cannot make any statement about the abdominal viscera. The film is not of diagnostic quality.

DR FRANSEEN: Is the mottling in the center merely an area of irregular bone destruction, with no evidence of trabeculation?

DR WYMAN: I interpret the mottling as bone destruction, with residual areas of medullary trabeculation and some areas of residual cortex remaining between the areas of destruction. I think the process may have started centrally and extended to involve the entire thickness of the bone.

DR FRANSEEN: The x-ray appearance is different from what I had visualized from the written description. I did not appreciate that the periosteal reaction was so far away from the main lesion.

To continue the discussion, I can say that I am not familiar with any giant-cell tumor that has taken on an appearance such as this even when a pathologic fracture has occurred through it. If we, then, go on to consider other primary malignant tumors, Ewing tumor must be thought of. In this respect, again, the age of the patient is very important. I know of no case of Ewing tumor in this age group, but as in any bone lesions, it can perhaps occur. I met Dr Simmons just before this conference and asked him if he remembered any patient with Ewing tumor in this man's age group, but he could remember none. Geschickter and Copeland\* have reported no case in a patient so old as this man. We have all seen bizarre x-ray pictures in Ewing tumor, but there is no suggestion here of lamination of the periosteum or the other signs that are usually

associated with this tumor. As you perhaps know, at least 50 per cent occur in adolescence, with tapering off of the age incidence at either end. The tumor rarely occurs in the thirties. Age in itself is a strong argument against a Ewing tumor in this case, but, again, one cannot exclude it entirely.

Multiple myeloma should be considered, but this patient at forty-eight is not too good a candidate for it. This lesion is not the purely destructive lesion by x-ray study that one usually associates with multiple myeloma, and to have an isolated lesion in an extremity without evidence elsewhere would be extraordinary in multiple myeloma. In this disease the serum protein is sometimes elevated, but we do not have this determination to help us. The character of the patient's pain, which showed remissions between aggravations by trauma, is suggestive of multiple myeloma in a general way, but these are about the only facts I can find in its favor. There was no Bence-Jones protein in the urine and no evidence of nephritis on urinalysis, the latter frequently accompany the lesion. So much for multiple myeloma.

Considering other malignant bone tumors, malignant tumors of cartilaginous origin usually show some trabeculation, and this lesion, according to the x-ray interpretation, gave no suggestion of trabeculation, but rather irregular mottled areas of destruction. The osteolytic form of osteogenic sarcoma must more seriously be considered in a destructive lesion such as this appeared to be. There was not enough new-bone formation to consider the osteoblastic form of osteogenic sarcoma. The osteolytic form can begin subcortically and, as it gets larger, extend to a more central position, as in this case. Pathologic fracture, as in this case, is common. However, osteogenic sarcoma, as Dr Simmons has pointed out so frequently, is uncommon at this age unless associated with Paget's disease. However, there is some overlapping of age groups, and osteolytic sarcoma cannot be excluded on the basis of age alone. Reticulum-cell sarcoma must also be considered, and I would be unable definitely to exclude this lesion without a biopsy. I see no reason to consider other bone-destructive lesions such as eosinophilic granuloma. I have had no personal experience with them, but know that they usually occur in much younger age groups, particularly in children.

In the neoplastic group, we are then left to consider secondary or metastatic lesions of bone. A secondary lesion of Hodgkin's disease taking this form, without any other evidence of it elsewhere, would be very uncommon because bone involvement of this type would usually occur only in late stages of the disease. I think we can disregard the lymph nodes described in the groins, because, in my experience, nodes of this description can be felt in almost any person, so that I see no reason for considering Hodgkin's disease seriously.

\*Geschickter, C. F., and Copeland, M. M. *Tumors of Bone*. 709 pp. New York: American Journal of Cancer, 1931. P. 640.

I think, however, that metastatic carcinoma must be considered very seriously, since the picture is entirely consistent with that diagnosis. In a woman, the breast would, of course, be regarded as a primary source, but this man's breast was presumably easily examined, and a carcinoma would have been discovered if present. The most common sources to consider in this case are the prostate and kidneys. Metastases from prostatic carcinoma are apt to show more osteoblastic activity than this lesion did, but some that we have seen have been almost completely osteolytic. An isolated metastasis like this in an extremity is uncommon in carcinoma of the prostate. Renal-cell carcinoma frequently produces a soft, pulsating tumor. In this case there is no description of the consistence of the tumor. The few that I have seen have been confined especially to the sternum and upper end of the humerus. This site, in the lower end of the humerus, is more unusual. The metastases from renal-cell carcinoma are often a more expanding type of tumor than this — this tumor mass was only 2.5 by 5.0 cm. That is as far as I can go, since nothing is said in the record about examination of the prostate or kidneys.

I had the impression as I first read through the record that the most likely diagnosis would be an osteolytic form of osteogenic sarcoma. On looking at the x-ray films, however, a metastatic lesion seems more likely. In any lesion like this, we have been taught that the only approach is to consider it a malignant lesion of bone until proved otherwise, and that the only method by which an exact diagnosis can be made is by biopsy with preparation for amputation if the lesion proves to be malignant. If I have to make a definite diagnosis from the appearance of the x-ray film, I say that this was probably metastatic carcinoma, and that is as far as I am willing to go.

#### CLINICAL DIAGNOSIS

Sarcoma, (?) reticulum-cell type

#### DR. FRANSEEN'S DIAGNOSIS

Metastatic carcinoma

#### ANATOMICAL DIAGNOSIS

Metastatic renal-cell carcinoma

#### PATHOLOGICAL DISCUSSION

DR. ENWIN F. CAVE: I saw this man after he had been admitted to the Baker Memorial Hospital. He was wearing a splint on the right arm. He had a fracture through the diseased area of the lower end of the humerus, and a good deal of swelling of the distal end of the arm and elbow. We could not make an accurate diagnosis, so we did a biopsy, separating the muscles, which were edematous.

The radial nerve was retracted, and we came into the fracture line. The bone was spongy and rather necrotic, the medulla was easily entered, and we took specimens from the cortex, the medulla and the periosteum. An attempt was made to do frozen sections at the time, but nothing conclusive was determined from the sections, so we closed the wound and waited for a report.

DR. TRACY B. MALLORY: The tumor in this case was extensively necrotic, and not until the permanent sections were cut were we able to find areas suitable for diagnosis. When we finally got some viable tumor it was quite evident that we were dealing with carcinoma, with large, clear, vacuolated cells very strongly suggestive of renal origin. Will you go on from there, Dr. Cave?

DR. CAVE: We debated then whether we should study the patient further by doing an intravenous pyelogram. Dr. Grantley Taylor was asked to see him, and he agreed that amputation was indicated and we proceeded with that. Amputation was done about two weeks after the biopsy. We amputated through the surgical neck of the humerus. The wound healed primarily. After that Dr. Chute and Dr. Colby saw the patient, and renal studies were done.

DR. MALLORY: Dr. Wyman, will you show the pyelogram?

DR. WYMAN: The pyelogram shows a tumor in the upper portion of the kidney, displacing the calyces.

DR. RICHARD CHUTE: I was presented with this problem on account of the fact that a number of cases have been reported in which a solitary metastasis from a renal-cell carcinoma has been removed and later the original source found and removed, and the patient remained "cured" for a good number of years. It seemed to us reasonable to extirpate the focus, therefore, Dr. Soutter and I did a nephrectomy. Dr. Soutter might like to say something about the technic and the result.

DR. LAMAR SOUTTER: This is the third case of a transthoracic nephrectomy done in this hospital for carcinoma. The reason for using this approach is that it provides more room for radical surgery. The exposure is better to cut the renal vein on the right side of the spine and the renal artery at the aorta and to remove the regional lymph nodes and the adrenal gland. That was done in this case.

DR. MALLORY: The amputated arm showed a mass of necrotic tumor, again with recognizable areas of renal-cell adenocarcinoma, and the resected kidney showed characteristic hypernephroma. The tumor was extensive enough to have invaded the renal vein and extended along nearly two thirds of the way to the vena cava as they often do.

The patient is still convalescing on the wards and is doing well.

## FEDERAL SUPPORT FOR MEDICAL EDUCATION

"THE philosophies of one age have become the absurdities of the next, and the foolishness of yesterday has become the wisdom of tomorrow" Half a century ago Osler<sup>1</sup> thus indicated the fluctuations of thought with which men sometimes measure their problems and devise their solutions. The problems are always vivid and immediate, whereas their solutions seem limited — so limited that men find themselves able to move in only one direction or not at all. Wars become inevitable, and so do Government subsidies, but is this wisdom or is it foolishness? Medical education in the United States is today based upon the highest standards in the world and yet whenever it is surveyed it is easily shown to be inadequate and in immeasurable need

of improvement. In a less prodigal age we should have said that we were living far beyond our means, but none is living beyond his means today until he has completely exhausted all chance of Government support. The air is full of talk of such support for medical students, medical research, medical education and medical practice.

The American Academy of Pediatrics has recently released a recommendation for federal support of pediatric education.<sup>2</sup> The figures presented are said to reveal a startling lack of adequate training on the part of those who are caring for children. On the other hand if such figures were broken down into groups of those whose hospital training or lack thereof was received ten, twenty and thirty or more years ago, it might become apparent that we are on the very crest of a wave of improvement in pediatric training as judged by time spent in pediatric hospitals after graduation from medical school. Certainly there are more candidates than there are opportunities for approved residency training in pediatrics, and in all the other specialties as well. When one turns to the need for more physicians trained in the care of children in the remote and rural areas, fellowships are suggested for medical graduates "committed to return to practice in an area of need." Many have tried, but no good answer has yet been framed for the old question of how they are to be kept down on the farm. The cost of medical education to the student is also cited as a reason why there may be a tendency on the part of young doctors to renounce special training or to settle in the urban areas where professional life may be economically easier. The recommendations are specific that an appropriation of \$5,000,000 be authorized, to be administered by the Federal Security Administration in direct support of pediatric education. Half of this would go to the departments of pediatrics of the approved medical schools in accordance with need and student enrollment. One and a half million dollars is recommended for scholarships and fellowships or other purposes directly related to pediatric education, and \$1,000,000 is recommended for allocation to states in need because of their remote and rural areas into which physicians cannot now be induced to move.

Other specialties occupy educational grounds no less valid and deserving, what would be the tendency for them to generate equalizing pressures? Medical schools are constantly being surveyed by professional groups gathering data about this or that special interest. Such surveys are generally followed by reports indicating the existing inadequacies and suggesting minimum standards. It is as though our leaders were busying themselves by seeking to perfect each small part of a mosaic, but neglecting to concern themselves with the over-all picture or the condition likely to supervene ten years hence.

That the eyes of different groups are not focused upon the same objective is emphasized by recent divergent estimates concerning the likelihood of a shortage of physicians by 1960.<sup>1</sup> The United States Public Health Service and the Federal Security Administration anticipate a shortage of between 30,000 and 50,000 doctors in another decade, whereas the American Medical Association estimates that by 1960 there will be in this country at least 1 physician for every 700 people—a greater ratio than at present or in the immediate past. The number of physicians is increasing at a relatively more rapid rate than that of the population as a whole. This would be all right if there were to be more for them to do in the coming era than there has been in the past. If there are to be vast increases in hospital and research facilities more medical manpower will be needed. On the other hand, too many physicians, like too many cooks, could be a menace to the people's health, especially if it is necessary to sacrifice quality to produce the larger number, and if they must eke out a living by private practice in this apprehensive and neurotic world.

Whether an extension or permanent modification of the present GI bill of rights for all medical students would be helpful (and to whom) is another large subject. Such an extension would not produce more doctors. It might make medical education available to students who would otherwise seek a different training or vocation. It would surely attract the type of student whose hat is in the ring for a scholarship. Medicine has need for the best brains that can be recruited; it also needs character. Brains are more easily measured than character,

but character motivates and guides the application of brainpower, and is therefore recognized as a raw material without which a good doctor cannot be educated regardless of the resources at his disposal. If a formula could be devised that would recognize and attract character as readily as brains are now recognized, medical educators would find the task of selecting students greatly lightened and better performed than at present.

Expansion of federal largess is potentially without limit—but there is a fly in the lard. The members of the medical profession are not unanimously convinced that Government support can be contrived without Government interference. In a recent Washington Report<sup>4</sup> an aide of the Federal Security Administrator is quoted as asking the question: "Why must Uncle Sam ever be suspected, when he lends a helping hand, of having something up his sleeve?" Whoever can answer this question can also tell us whether all this is wisdom or foolishness.

#### THE WORLD MEDICAL ORGANIZATION

POSSIBLY unnoticed by many, in the present confused and disturbed condition of the world, was the announcement from the recent Interim Session of the House of Delegates of the American Medical Association in Cleveland on the formation of a World Medical Organization.

This was agreed to in principle at the Atlantic City Annual Session in June, 1947, and authority for participation wholeheartedly voted by the House of Delegates. The organization meeting was held in Paris in September, with four members of the Board of Trustees as the American representatives. One hundred and twenty-five delegates from forty-eight nations attended. From the reports on the sessions, one gathers that some of the meetings resembled those held by the United Nations at Lake Success. Apparently, there were many trying moments when 'patience, tolerance, long-suffering

**FISH** — John E. Fish, M.D., of Canton, died on March 30. He was in his seventy-fifth year.

Dr. Fish received his degree from Dartmouth Medical School in 1896. He was a former president of Norfolk District Medical Society and was formerly superintendent of the Massachusetts Hospital School in Canton. He was a fellow of the American Medical Association.

His widow, two daughters and two sons survive.

**HOSLEY** — Walter A. Hosley, M.D., of Topsfield, died on March 25. He was in his seventieth year.

Dr. Hosley received his degree from Harvard Medical School in 1904.

Two daughters survive.

**HUNT** — Reid Hunt, M.D., of Boston, died on March 7. He was in his seventy-eighth year.

Dr. Hunt received his degree from College of Physicians and Surgeons of Baltimore in 1896. He was associate professor of pharmacology at Johns Hopkins University School of Medicine from 1898 to 1903, chief of the division of pharmacology, United States Public Health Service, from 1904 to 1913 and professor of pharmacology at Harvard Medical School from 1913 to 1936. He was professor of pharmacology, emeritus, Harvard Medical School, a former chairman of the Council on Pharmacy and Chemistry of the American Medical Association and a member of the Association of American Physicians.

His widow survives.

**IRWIN** — Vincent J. Irwin, M.D., of Springfield, died on February 26. He was in his sixty-first year.

Dr. Irwin received his degree from Yale University School of Medicine in 1909. He was a member of the American Academy of Ophthalmology and Oto-Laryngology and a fellow of the American Medical Association.

His widow survives.

**LELAND** — Leslie P. Leland, M.D., of Worcester, died on March 16. He was in his sixty-fourth year.

Dr. Leland received his degree from Boston University School of Medicine in 1909. He was a former secretary of the Worcester District Medical Society and was a member of the New England Obstetrical and Gynecological Society and a fellow of the American Medical Association.

His widow and two daughters survive.

**MAY** — James V. May, M.D., of Belmont, died on December 24, 1947. He was in his seventy-fifth year.

Dr. May received his degree from University of Pennsylvania School of Medicine in 1897. He was a former president of the New England Society of Psychiatry, Massachusetts Psychiatric Society and American Psychiatric Association, and was a fellow of the American Medical Association.

**O'BRIEN** — John C. O'Brien, M.D., of Greenfield, died on March 18. He was in his eighty-fifth year.

Dr. O'Brien received his degree from University of Vermont College of Medicine in 1887. He was formerly a trustee of the Northampton State Hospital, town physician and physician to the Greenfield House of Correction, and was a fellow of the American Medical Association.

A son and a daughter survive.

## MEDICOLEGAL ABSTRACT

**Relation of Patient and Physician — Confidential communications and their possible disclosure in hospital records.** According to the terms of his oath the physician is bound to treat the communications of his patient in confidence. Legally, however, no such privilege existed under the common law. In some states, however, statutes have protected confidences revealed to the physician

for the purpose of adequate diagnosis and treatment. In states where such confidences are protected by statute the question may arise to what extent, if any, the protection is removed if the information revealed to the physician in confidence is made a part of a hospital record. Such a question was recently considered by the Supreme Court of Ohio.

In a proceeding in which it was sought to show that a will was invalid on the ground that the testator lacked the necessary mental capacity, hospital records were offered, consisting of the entrance slip, the physician's direction for the medication to be administered and treatment to be given the patient by the nurses, record of analyses of the blood and the urine of the patient and the day-to-day chart made and kept by the nurses who had charge of the patient while he was at the hospital. These charts recorded the food and medicine given and the condition and behavior of the patient, the fact that he was irrational at times, that he left his bed at unreasonable hours, that on one occasion he used a wastepaper basket as a commode, and that on several occasions he became unruly. Part of the record included notations of increasing administrations of sedatives culminating on the date that the will was signed. These portions of the record were all admitted in evidence. A verdict was returned that the writing in question was not valid as the last will and testament of the deceased, and judgment was entered for the contestant. The contestees sought a reversal on the grounds that the hospital record contained matters communicated confidentially to the physician and nurses of the deceased and should not have been admitted in evidence.

Ohio has statutes establishing a patient-physician privilege and also providing for the admissibility of hospital records, but the statutes do not specify the relation between the two. The court discussed the question whether or not the communications should have been admitted even though it found that the contestees had waived their privilege by permitting the physician to testify completely and without objection to all details of his diagnosis and treatment. However, the court stated:

The courts in most states having Physician-Patient Privilege Statutes similar to section 11494, General Code, generally hold that communications between Physician and Patient, not in the presence of third persons, for the purpose of diagnosis and treatment of the patient, if carried into a private hospital record or chart, remain confidential, and that such part of the chart or record is inadmissible in evidence unless the privilege is waived.

In discussing generally the admissibility of hospital records the court said:

Such a hospital or physician's office record may properly include case history, diagnosis by one qualified to make it, condition and treatment of the patient covering such items as temperature, pulse, respiration, symptoms, food and medicine given, analysis of the tissues or fluids of the body, and the behavior of and complaints made by the patient.

The court drew a line between direct communication and observed facts or information obtained without communication. The difficulties in determining admissibility according to such a line of demarcation are evident. Portions of the record that report diagnosis and directions for treatment do not fall into either of the categories described by the court. Is the diagnosis admissible? And of what use is it to bar the communications on which diagnosis is based when the diagnosis and medication and directions for treatment clearly indicate the substance of the barred communication? In this case, therefore, part of the records included notations of increasing administration of sedatives that would be confidential if related to the physician by the patient but perhaps avoids the privilege when entered on the hospital record as an observed fact.

If the entire hospital record is admissible in evidence the purpose of the statute and of the physician's oath would be nullified, and professional confidence would be limited to unrecorded information (*Wes v. Wes*, 72 N. E. [2nd] 245, 1947).

## MISCELLANY

### AMERICAN COLLEGE OF SURGEONS APPROVES USE OF NURSE ANESTHETISTS

The Board of Regents of the American College of Surgeons at a meeting on February 21 adopted the following resolution:

The American College of Surgeons regards with deep concern the actions of some physician anesthesiologists in giving the impression to the lay public press that it is unsafe for experienced nurse anesthetists to conduct surgical anesthesia. While it supports the increasing tendency of having physician anesthesiologists in charge of surgical anesthesia it deplores at this time any propaganda for the elimination of the trained nurse anesthetist. On the contrary, the American College of Surgeons is of the opinion that, in view of the inadequacy in number of the physician anesthesiologists and in view of the splendid record of achievement of the nurse anesthetists institutions engaged in the training of nurses for this purpose should be encouraged to continue their programs.

### NATIONAL CANCER INSTITUTE

More than \$1,355,818 in federal grants in aid from Public Health Service funds for cancer research and control has been announced by the Federal Security Administration. It was made on the recommendation of the National Advisory Cancer Council of the National Cancer Institute. Another \$8,000,000 in construction grants for new laboratory and clinical facilities has been recommended by the Council.

## NOTE

Dr. Arthur Marvel Laseck, head of the Department of Anatomy, Medical College of the State of South Carolina in Charleston since 1933, has been appointed Waterhouse Professor of Anatomy at Boston University School of Medicine effective July 1. Dr. Laseck will succeed Dr. Jesse LeRoy Conel, a member of the medical faculty since 1923.

## CORRESPONDENCE

### RESTORATION OF LICENSE

To the Editor: At a meeting of the Board of Registration in Medicine held March 18 it was voted to restore the registration to practice medicine to Dr. George J. Orlandi, 20 Charlotte Road, Newton Centre (formerly of 1234 Blue Hill Avenue, Dorchester).

H. QUINBY GALLUP, M.D., Secretary

State House  
Boston

## DEPRIVATION OF LICENSE

To the Editor: At a meeting of the Board of Registration in Medicine held March 18 it was voted to suspend the registration of Dr. William P. Pratt, 28 Adams Street, Quincy for three months.

H. QUINBY GALLUP, M.D. Secretary

State House  
Boston

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*An Atlas of Anatomy*. By J. C. Boileau Grant, M.C. M.B. Ch.B. F.R.C.S. (Edin.) professor of anatomy in the University of Toronto. Second edition. 4 cloth, 496 pp. with 91 illustrations. Baltimore: Williams and Wilkins Company. 1947. \$10.00.

This atlas was published first in 1943 and reprinted in 1944 and 1945. Dr. Grant to this edition has added more than two hundred illustrations including the wrist, superficial veins of the limbs, the inguinal region, abdominal viscera, suprarenal gland, smooth and the blood supply of the esophagus, stomach, duodenum, pancreas, bile passages, spleen and suprarenal glands. Also the more common dissecting room variations, the epiphyses and schemes of the distribution of the cranial nerves and of the motor nerves to the extremities are considered. A good index concludes the volume. The book is well published in every way. The illustrations and color work are excellent. The atlas is recommended for all medical libraries.

*Overcoming Stammering*. By Charles Pellmar. With a foreword by Frederic Martin, M.D., director of National Institute for Voice Disorders, Bristol, Rhode Island, and director of Speech Clinics, State Department of Education, Rhode Island. 8° cloth, 160 pp. New York: The Beechurst Press. 1947. \$3.00.

Mr. Pellmar, an experienced practicing speech correctionist, analyzes and evaluates current methods of speech correction and treatment. He presents a plan for speech correction of stammering and stuttering based upon the physiology of speech and proper mental hygiene, rather than on the functioning of the speech apparatus. His method may be used in the home by intelligent parents. The text deals with an autobiographic sketch of a stammerer by Aaro Pellmar. A list of books and an index conclude the volume. The book is well published. It is recommended for medical and educational libraries.

*Procedure in Examination of the Lungs with Especial Reference to the Diagnosis of Tuberculosis*. By Arthur F. Kraetzer, M.D., associate attending physician, Lenox Hill Hospital, physician to outpatients, New York Hospital and instructor in medicine (dermatology), Cornell University Medical College. Third edition revised and with a preface by Jacob Segal, M.D., medical director, Los Angeles Sanatorium. Oxford Medical Publications. 8° cloth, 150 pp. with 16 illustrations and 14 plates. New York: Oxford University Press. 1947. \$3.50.

Dr. Segal, in this revision of Kraetzer's manual has brought the subject up to date since the publication of the previous edition in 1935. The text of the second edition has not been disturbed but the new material has been incorporated in an appendix of twenty-two pages and sixteen x-ray plates. An x-ray commentary on the correlation of signs leading to a diagnosis with histories of 13 cases and illustrated with the x-ray pictures is included in the appendix. An index has been added for the first time. The volume is well printed with good type on good paper.

*The Dispensatory of the United States of America* By Arthur Osol, Ph G, M S, Ph D, professor of chemistry and director of the department of chemistry, Philadelphia College of Pharmacy and Science, and George E Farrar, Jr, M D, associate professor of medicine, School of Medicine, Temple University, and chief of Medical Service A, Episcopal Hospital 4<sup>th</sup>, cloth, 1928 pp Philadelphia J B Lippincott Company, 1947 \$16 50

This standard reference work has a remarkable record of one hundred and fifteen years of continuous publication. It was first issued in 1833 as *The Dispensatory of the United States of America*, by Drs George B Wood and Franklin Bache. In 1879, with the fourteenth edition, Dr H C Wood became associated with the elder Dr Wood, and in 1885, with the fifteenth edition, Dr H C Wood became the principal author. With the centennial edition Dr H C Wood, Jr, became the principal author, and he is now advisory editor to this twenty-fourth edition. The work was issued every few years from the beginning, and a number of editions were reprinted, except that editions were not published during the Civil War years, 1859-1864. The text is divided into five parts. Parts one and two, the major portion of the work, describe the drugs recognized by the *United States Pharmacopæia*, the *Pharmacopæia of Great Britain* or the *National Formulary* and the drugs not official in these works. The drugs are listed alphabetically in these two sections. The remaining parts list general tests, processes, reagents and solutions, veterinary uses and doses of drugs, and tables of the *United States Pharmacopæia* or the *National Formulary*. The tables on atomic and molecular weights, and on equivalents of weights and measures are especially valuable. A comprehensive index concludes the volume. The publishing is excellent in every way. Every effort has been made to reduce the weight and size of such a large volume. The text is printed in two columns on a good light paper with a good type. The price is very reasonable for the size of the book. The work is recommended for all libraries, medical and general, and to all persons interested in drugs.

*The Foot and Ankle. Their injuries, diseases, deformities and disabilities* By Philip Lewin, M D, associate professor of bone and joint surgery, and acting head of department, Northwestern University School of Medicine, professor of orthopedic surgery, Post-Graduate Medical School of Cook County Hospital, attending orthopedic surgeon, Cook County Hospital, senior attending orthopedic surgeon, Michael Reese Hospital, and consulting orthopedic surgeon, Municipal Contagious Disease Hospital, Chicago. Third edition 8<sup>th</sup>, cloth, 847 pp, with 389 illustrations. With line drawings by Harold Laufman, M D. Philadelphia Lea and Febiger, 1947 \$11 00

This edition of a standard work has been extensively revised in the light of the vast amount of information gleaned from the records and experience of World War II. Much material has been added, and emphasis has been placed on compound fractures, crushing wounds and osteomyelitis. There is a special chapter on the military aspects of foot and ankle disorders. The sections on traumatic gangrene and amputations have been enlarged, and ringworm has been considered not only as a primary and sole infection but also as a complication of injuries. There is a special chapter on psychosomatic medicine as it relates to certain orthopedic conditions. The book is well published and is recommended for all medical libraries and to all persons interested in the subject.

*Diseases of the Nose, Throat and Ear* By William L Ballenger, M D, and Howard C Ballenger, M D, associate professor and acting chairman, Department of Otolaryngology, Northwestern University School of Medicine, Chicago, and surgeon, Department of Otolaryngology, Evanston Hospital, Evanston, Illinois. Assisted by John J Ballenger, M D, research fellow in otolaryngology, Northwestern University School of Medicine, Chicago. Ninth edition 8<sup>th</sup>, cloth, 993 pp, with 597 illustrations. Philadelphia Lea and Febiger, 1947 \$12 50

This edition of an authoritative textbook has been revised by the addition of much material. Obsolete material has been deleted, and portions of the text rewritten and amplified. There is a new chapter on "headaches and neuralgias of the face," and rhinoplastic reconstruction has been described. The special contributors have revised the chapters on arytenoidectomy for bilateral paralysis of the current laryngeal nerves,

physiology and functional tests of the labyrinth and inflammatory diseases of the labyrinth and peroral endoscopy. The volume is well published in every way. The printing of a history of the editions on the back of the title page would be of value to reviewers and other interested persons. The book is recommended for all medical reference collections.

*Textbook of General Surgery* By Warren H Cole, M D, professor of surgery and head, Department of Surgery, University of Illinois College of Medicine, and director of surgical service, Illinois Research and Educational Hospitals, Chicago, and Robert Elman, M D, professor of clinical surgery, Washington University School of Medicine, assistant surgeon, Barnes Hospital, associate surgeon, St. Louis Children's Hospital, and director of surgical service, H G Phillips Hospital, St. Louis. Fifth edition 8<sup>th</sup>, cloth, 1160 pp, with 558 illustrations. New York D Appleton-Century Company, 1948 \$11 00

This standard textbook, first published in 1939 and last revised in 1944, in this new edition has been thoroughly revised to date. The type has been completely reset, and the volume repaged. The chapters on war and catastrophe surgery, surgical diseases of the chest and chemotherapy have been rewritten. The chapter on the nutritional requirements of surgical patients has been considerably expanded. A chapter has been added on surgical convalescence, including preoperative and postoperative care. The text is well written, and the material well organized. Selected references are appended to each chapter. Indexes of authors and subjects conclude the volume. The publishing is excellent except that the coated paper makes the volume heavy for its size. It is recommended for all medical libraries and all surgeons.

*A Text-Book of Bacteriology* By R W Fairbrother, M D, D Sc (Man), F R C P (Lond), director of the department of clinical pathology, Manchester Royal Infirmary, and special lecturer in bacteriology, University of Manchester. Fifth edition 8<sup>th</sup>, cloth, 480 pp, with 34 tables and 6 plates. New York Grunc and Stratton, 1948 \$6 50

This textbook, first published in 1937, and last revised in 1946, has gone through twelve printings of the five editions, a fact that attests its soundness as a textbook for students. The author has made a thorough revision of the text for this fifth edition. The book is an outline of the medical aspects of bacteriology. The material is divided into three parts: general bacteriology, systematic bacteriology and general technique. A good index concludes the volume, which is well printed with a good type by the lithographic process on light paper.

*Blood Pressure and Its Disorders, including Angina Pectoris* By John Plesch, M D, Budapest, M D, Germany, L R C P and S Edin and Glas. Second edition revised and enlarged 8<sup>th</sup>, cloth, 307 pp, with 125 illustrations. Baltimore Williams and Wilkins Company, 1947 \$6 00

Dr Plesch has revised this second edition of his monograph, first published in 1944, by the addition of material, chapters and case histories. Selected references have been appended to each chapter. The text represents the author's personal experience and research, and is not intended as a comprehensive treatise on the subject. The printing was done in Great Britain and is excellent. The type and paper are good. The book should prove useful to physicians interested in the subject.

*Biochemistry for Medical Students* By William V Thorpe, M A (Cantab), Ph D (Lond), reader in chemical physiology, University of Birmingham. Fourth edition 8<sup>th</sup>, cloth, 496 pp, with 36 illustrations. Baltimore Williams and Wilkins Company, 1947 \$5 00

This English textbook, first published in 1938, and last revised in 1943, has been revised to date. A chapter on the use of isotopes in biochemical investigations has been added, and the sections on protein structure, coenzymes, flavoproteins, bile pigments and nutrition in wartime have been largely rewritten. The text is well written, and the material well organized. The type, printing and paper are excellent. The book should prove useful as an excellent summary of the subject.

*Malaria, with Special Reference to the African Forms.* By W. K. Blackie M.D., Ph.D., F.R.C.P. (Edin.), D.T.M. & H. 8°, cloth 104 pp., with a color plate. Cape Town: The African Bookman for the Post-Graduate Press 1947 10s.6d.

This concise monograph presents the latest methods of treatment with quinine and the newest plasmodial drugs including mepracine (atabrine), pamaquin and paludrine. The first chapter comprises a short historical review, followed by chapters on the parasitology, pathology, clinical features, diagnosis, prognosis, treatment and prophylaxis of the various types of the disease. The material is well organized and well published in every way. The color plate depicting the various plasmodiae is excellent. A good index concludes the text. The monograph was published by the Bayer Pharma publication fund of the Cape Town Post Graduate Medical Association. The work is recommended for all medical libraries.

*Nursing in Modern Society.* By Mary Ella Chayer, R.N. M.A. associate professor of nursing education. Teachers College, Columbia University. 8°, cloth 288 pp. New York: G. P. Putnam's Sons 1947 \$4.00.

This book has been written primarily for nurses, teachers and supervisors. The various current problems of nursing are discussed by the author in the following divisions: the impact of social forces upon nursing, the influence of social forces upon community health needs and building a better future for the nursing profession. Miss Chayer has called attention to the changing needs of society and to the changes that have already taken place in the nursing profession. The last chapter summarizes the twelve cardinal principles of professional service. The text is well written in an easy style and the material is well organized. The type paper and printing are excellent. A list of references and one of questions for study are appended to each chapter. A comprehensive general bibliography and a good index conclude the volume. The work should prove useful as a reference work to schools of nursing and as a textbook for postgraduate students. It is recommended for the reference collections of all medical libraries.

*Benjamin Silliman, 1779-1864. Pathfinder in American Science.* By John F. Fulton, M.D. and Elizabeth H. Thomsen. 8°, cloth, 294 pp. with seventeen illustrations. New York: Henry Schuman, 1947 \$4.00.

Benjamin Silliman is of interest to the medical historian because of the responsible part he took in organizing Yale University School of Medicine in 1813. He was eminent as a chemist and geologist and as a teacher of science. He established the great Peabody Museum of natural history and founded the first gallery of fine arts in an American academic institution, the Trumbull Gallery of Yale College. He was also largely instrumental in founding the Sheffield Scientific School, first called the School of Applied Chemistry. The authors of this well written biography for the general reader cover the professional life of Silliman from the time he was appointed professor of chemistry at Yale in 1802 until his retirement in 1853. The story is told in an easy narrative style. The book is well published and should be in all medical and scientific historical collections. It is one of a series in *The Life of Science Library*.

*400 Years of a Doctor's Life.* Collected and arranged by George Rosen M.D. and Beate Caspari-Rosen M.D. 8°, cloth, 429 pp. New York: Henry Schuman 1947 \$5.00.

This interesting anthology is made up of excerpts taken from formal autobiographies, letters and other writings of physicians, dead and living of the past four hundred years. The material is arranged according to epochs and incidents in a doctor's life: early years, school days, medical student days, the practice of medicine, scientist, scholar and teacher, the doctor marries, the doctor as a patient, the doctor goes to war, writing and politics and reflections on life and death. The selections are preceded by short biographic notes or comments. The absence of direct references to the sources of the selections will be deemed by the historian and bibliographer. A number of physicians appear more than once in different sections of the text and there should have

been an index in names to make the book useful as a reference work. The type, printing and paper are excellent. This unusual historical book should be in all collections of medical and general history.

*Calcium and Phosphorus in Foods and Nutrition.* By Henry C. Sherman Ph.D., Mitchell Professor of Chemistry, Rutgers University. 8°, cloth 176 pp., with seven figures and twelve tables. New York: Columbia University Press, 1947 \$2.75.

This semipopular monograph presents in plain language a summary of the place of calcium and phosphorus in present day nutrition. The first chapter discusses the role of calcium and phosphorus in nature in agriculture and in human nutrition. The following chapters deal with calcium in the body, the effects of food and growth upon the calcium content, chemical forms and nutritional functions of phosphorus, calcium and phosphorus requirements and the problem of necessary and optimal intakes and foods as a factor in the nutritional provision of calcium and phosphorus. An extensive bibliography of forty four pages is appended to the text. A good index concludes the volume. The text is well written in a pleasing style and the material is well organized. The publishing is excellent. The printing is well done with a good type on a good light paper. The volume is recommended for all medical and general libraries and to all persons interested in the subject.

*Surgical Disorders of the Chest. Diagnosis and treatment.* By J. K. Donaldson M.D. associate professor of surgery and in charge of thoracic surgery, University of Arkansas School of Medicine and member of surgical staff, St. Vincent's Infirmary and visiting staff, Baptist Hospital, Little Rock, Arkansas. Second edition thoroughly revised. 8°, cloth, 485 pp. with 146 illustrations and 2 color plates. Philadelphia: Lea and Febiger 1947 \$8.50.

This new edition of a standard treatise has been revised to include the knowledge gained during World War II. Decontamination of the lung is discussed in some detail. Selected references are appended in each chapter, and a good index concludes the volume. The publishing is excellent in every way. The book is recommended for all medical libraries and to surgeons interested in the subject.

*Principles of Occupational Therapy.* Edited by Helen S. Willard A.B. O.T.R. director, Philadelphia School of Occupational Therapy and Clare S. Spackman S.M. in Ed., O.T.R. director, curative workshop, Philadelphia School of Occupational Therapy, director, Occupational Therapy Department, Hospital of the Graduate School of Medicine, University of Pennsylvania, and assistant director, Philadelphia School of Occupational Therapy. 8°, cloth 416 pp. with 46 illustrations. Philadelphia: J. B. Lippincott Company 1947 \$4.50.

This new textbook is the joint work of twenty specialists in the field of occupational therapy. The text is divided into two sections: basic concepts and applied principles. The first section deals with the history, development, scope, educational aims and activities of the subject, and factors in the organization of occupational therapy departments. The second section discusses the place of the therapy in general and special hospitals with a chapter on children's hospitals and pediatric services and in United States Army and Navy hospitals during World War II. In this section there are chapters on the use of occupational therapy for patients with mental disease and tuberculosis, the visually handicapped and for patients with physical injuries. The last chapter of over a hundred pages is subdivided into three sections, dealing with treatment for limitation of motion of joints, flaccid paralysis and industrial injuries, for patients afflicted with cerebral palsy and for arthritic patients. The treatment is given in detail. The concluding chapter describes the rehabilitation program of the Veterans Administration. The work constitutes a treatise on the philosophy and practice of the subject. The text is well written, and the organization of the material is good. The volume is well published. The type is good and legible, and the printing on a soft light paper pleasing to the eye, is excellent. The book should be in all medical libraries and should prove valuable to all persons interested in physical therapy.

*A Text-Book of Mental Deficiency (Amentia)* By A F Tredgold, M D, F R C P, F R S (Ed), consulting physician to University College Hospital, London Seventh edition 8°, cloth, 534 pp., with 47 plates and 9 tables Baltimore Williams and Wilkins Company, 1947 \$8 50

This new edition of a standard textbook, last revised in 1937, has been brought up to date by the addition of considerable material Some chapters have been rewritten, and the changes made by the British Education Act of 1944 relating to educationally subnormal and defective children have been incorporated in the chapter on English law concerning mental defectives A good index concludes the volume The text, printed in Great Britain, is well done with a good type on good paper The book is recommended for all medical libraries and to all persons interested in the subject

## NOTICES

### ANNOUNCEMENT

Dr Franklin G Balch, Jr, announces the removal of his office to 1180 Beacon Street, Brookline, for the practice of general surgery

### SUFFOLK DISTRICT MEDICAL SOCIETY

The Suffolk District Medical Society will meet in Sprague Hall, Boston Medical Library, 8 Fenway, Boston, on Tuesday, May 4 The councilors will meet at 3 30 p m, and the annual meeting will be held at 5 00 p m

### MASSACHUSETTS SOCIETY FOR SOCIAL HYGIENE

The annual meeting of the Massachusetts Society for Social Hygiene will be held at a dinner at the Boston City Club, 14 Somerset Street, Boston, on Wednesday, April 28, 6 00 p m *Guest speaker* Dr Raymond A Vonderlehr of Atlanta, Georgia, medical director, Communicable Disease Center, United States Public Health Service, will speak on the subject "Past, Present and Future Responsibilities of the Social Hygiene Societies in the Control of the Venereal Diseases" Dr William A Hinton, chief of the Wassermann Laboratory, State Department of Public Health, and chief of the Laboratory Division of the Boston Dispensary, will be another guest of honor at the dinner Dr George Gilbert Smith will preside

The public is cordially invited to attend For details regarding the program, reservations for the dinner and so forth, application should be made in writing or by telephone to the office of the Massachusetts Society for Social Hygiene, 1145 Little Building, HANcock 6-3176

### NEW ENGLAND HEART ASSOCIATION

A meeting of the New England Heart Association will be held in the auditorium, Boston University School of Medicine, 80 East Concord Street, Boston, on Monday, April 26, at 8 15 p m Dr James M Faulkner will preside

#### PROGRAM

Diphtheritic Myocarditis Drs Norman H Boyer and Louis Weinstein

Clinical and Laboratory Features of First Attacks of Rheumatic Fever Occurring in Scarlet-Fever Patients Treated with Penicillin Drs Louis Weinstein, Louis Bachrach and Norman H Boyer

Acceleration of Flow in the Veins of Human Limbs by the Local Application of Pressure Drs Joseph R Stanton, Edward D Freis and Robert W Wilkins

Some Observations Concerning the Effect of Sympathectomy on the Human Heart Rate Drs Reginald H Smithwick, Earle M Chapman, Dera Kinsey and George P Whitelaw

The Effects of Veratrum Viride in Hypertensive Man Drs Edward D Freis, Joseph R Stanton, James W Culbertson, Julius Litter and Meyer H Halperin

Interested physicians and medical students are cordially invited to attend

### NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

The regular meeting of the New England Society of Physical Medicine will be held at the Ring Sanatorium and Hospital, Arlington, Massachusetts, on Wednesday, April 21, at 8 p m Dr Volta R Hall will speak on the topic "Physical Medicine in the Treatment of Psychiatric Conditions"

Members of the medical profession are cordially invited

### AMERICAN CLINICAL AND CLIMATOLOGICAL ASSOCIATION

The annual meeting of the American Clinical and Climatological Association will be held at White Sulphur Springs, West Virginia, from November 1 to 3 (secretary, James Bordley, III, M D, Mary Imogene Bassett Hospital, Cooperstown, New York)

### AMERICAN CONGRESS OF PHYSICAL MEDICINE

The twenty-sixth annual scientific and clinical session of the American Congress of Physical Medicine will be held from September 7 to 11, inclusive, at the Hotel Statler, Washington, D C Scientific and clinical sessions open to members of the medical profession in good standing with the American Medical Association will be given

Full information may be obtained by application to the American Congress of Physical Medicine, 30 North Michigan Avenue, Chicago 2, Illinois

### AMERICAN NEUROLOGICAL ASSOCIATION

The annual meeting of the American Neurological Association will be held in Atlantic City, New Jersey, from June 14 to 16, with headquarters at the Claridge Hotel (secretary-treasurer, H Houston Merritt, M D, Montefiore Hospital, Gun Hill Road, New York 67, New York)

### AMERICAN SOCIETY OF ANESTHESIOLOGISTS INC

A joint meeting of the American Society of Anesthesiologists, Inc, and the Western Divisions of the Canadian Anaesthetists' Society will be held at the Hotel Saskatchewan, Regina, Saskatchewan, Canada, on April 23 and 24

Physicians and medical students are invited

### MAINE MEDICAL ASSOCIATION

The annual meeting of the Maine Medical Association will be held in Poland Spring from June 20 to 22 (secretary, Frederick R Carter, M D, 142 High Street, Portland 3, Maine)

### MINNESOTA STATE MEDICAL ASSOCIATION

The annual meeting of the Minnesota State Medical Association will be held in Minneapolis from June 7 to 9 (secretary, B B Souster, M D, Lowry Medical Arts Building, St Paul 2, Minnesota)

### MONTANA STATE MEDICAL ASSOCIATION

The annual meeting of the Montana State Medical Association will be held in Billings on June 18 and 19 (secretary, H T Caraway, M D, 115 North 28th Street, Billings, Montana)

### NEW MEXICO MEDICAL SOCIETY

The annual meeting of the New Mexico Medical Society will be held in Las Vegas from June 3 to 5 (secretary, H L January, M D, 221 West Central Avenue, Albuquerque, New Mexico)

(Notices concluded on page xiii)

## CARCINOMA OF THE STOMACH\*

CLAUDE E. WELCH, M.D.,† AND ARTHUR W. ALLEN, M.D.‡

BOSTON

**S**URGICAL experience with carcinoma of the stomach at the Massachusetts General Hospital has been reviewed by Parsons<sup>1</sup> in previous papers covering the years 1922 to 1926, and the period from 1927 to 1936 by Parsons and Welch.<sup>2</sup> This report includes all patients admitted to this hospital on whom the diagnosis was made during the ten-year period 1937 to 1946 inclusive.

In the compilation of these figures, it is, of course, our hope to show that increased knowledge of the disease and its amenability to surgical attack have resulted in a steadily increasing five-year salvage rate. But it is of equal importance to consider the trends in management of patients with cancer of the stomach. In this brief summary, only our own experience can be considered, and no attempt is made to cover the voluminous literature comprehensively.

Several methods can be listed by means of which the curability rate can be increased. They are as follows: earlier diagnosis, that more patients with carcinoma will arrive in the hospital in a curable stage, more radical approach to the problem of gastric ulcer, that a certain number of cancers masquerading as ulcers will not be overlooked, extension of the type of operation so that by a wider excision of involved tissue, more cures may be obtained, and a reduction in the postoperative mortality, so that cases favorable for cure are not lost.

### DELAY BEFORE TREATMENT

Theoretically, if all patients were subjected to resection as soon as carcinoma of the stomach developed, all would be cured. Early diagnosis is therefore of the utmost importance. A vivid illustration of this point is furnished by the following case.

F. C. (M.G.H. 61931) a 58-year-old man, entered the hospital on June 27, 1934, because he had vomited blood three times in the previous month. X-ray studies, including

an upper gastrointestinal series were negative. Gastroscopy showed chronic gastritis. Because of the possibility of carcinoma of the stomach, exploratory operation was performed. A 2-cm lymph node found on the greater curvature, on frozen section showed highly malignant carcinoma. Because metastasis was already present, the surgeon did only a local excision of a small carcinoma of the greater curvature, and did not remove any other lymph nodes. The pathological report was adenocarcinoma. The patient was living and well 12 years later. Despite the high malignancy of the tumor and an inadequate operation, early surgery effected a cure.

Cancer of the stomach, once established, is usually a very rapidly growing tumor. This is shown by the rarity of cancers of the stomach discovered incidentally at post-mortem examination, when death is due to some other cause. This behavior is in contrast to that of carcinoma of the prostate, which is not uncommonly discovered in autopsy specimens as an incidental finding.

This behavior of carcinoma of the stomach has been recognized for many decades, and a vast amount of educational information has been spread by various cancer-control groups in an effort to bring the patient with gastric symptoms to the surgeon in time for cure. At the same time, the medical profession has become more alert to the problem, and early diagnosis has been facilitated by better x-ray films and an increased use of the gastroscopy.

It seemed probable, therefore, that a comparison of the delay before treatment would show a significant decrease in this last decade. To obtain comparable series, the length of time that elapsed from the onset of gastric symptoms to the date that the patient entered the hospital for treatment was determined for all patients undergoing operation during the twenty-year period 1927 to 1946. The delay in the first ten-year period was then contrasted with that in the latter (Fig. 1). The remarkable and unhappy result is that the two curves can be almost exactly superimposed.

Why does the average delay before treatment still remain at the high level of five months? Is it apathy on the part of the patient or neglect by the physician? One is inclined to believe that all

educational efforts have been negated by the radio and advertising columns with their promises of "relief for acid indigestion." Perhaps the medical profession should be satisfied that it is not fighting a losing battle against this propaganda, and conclude that if the public wishes to be cured of cancer of the stomach, it had better do something to aid itself.

No special attempt has been made in this study to discover the length of life of the untreated cases. It has been shown by Nathanson and Welch<sup>3</sup> and by Livingston and Pack<sup>4</sup> that the average duration

Allen and Welch,<sup>6</sup> in a review of gastric ulcers observed at the Massachusetts General Hospital from the years 1931-1940, found that 14 per cent of ulcers first considered to be benign were later proved to be malignant. No certain method could be found to differentiate the two types of lesions, but some conclusions were drawn that serve as a guide in therapy.

Immediate surgery is recommended in patients with a gastric ulceration under any one of the following conditions: if the ulcer is of short duration and the patient is over fifty years of age, if the ulcer is over 2.5 cm. in diameter, if there is no free hydrochloric acid in the stomach, if the ulcer is in the greater curvature or on the prepyloric region, and if the ulcer is chronic or recurrent and on the lesser curvature. Hospital observation and medical treatment for one month are advised if the lesion is acute and in a young patient, is under 1 cm. in diameter and is in the lesser curvature or on the anterior or posterior wall. If, in the last group, healing is not complete in a month, surgery is advised.

FIGURE 1 Delay in Seeking Treatment among All Cases of Cancer of the Stomach in Which Operation Was Performed. The duration of symptoms before hospital admission is divided into ten-year periods.

of life is about a year from onset of symptoms, and that 90 per cent of all patients are dead at the end of two years. The average delay from onset of symptoms to hospital entry of patients not subjected to surgery in the present series was about six months, at that time, operation was judged unwise or was refused by the patient.

Once the patient has been admitted to the hospital, he is studied completely. Endoscopy, as Benedict<sup>5</sup> has shown, is of great value, especially with lesions high in the stomach, since esophageal involvement may be observed. Peritoneoscopy is often valuable, especially if the patient has no symptoms of obstruction. If hepatic or peritoneal metastases are found, in the absence of obstruction, an operative procedure is contraindicated. On the other hand, if obstruction is present, the exploration is nearly always recommended, even if metastases are present, in the hope that a short-circuit may make the patient's life more comfortable.

The therapeutic procedures employed in the various periods are listed in Table 1.

THE PROBLEM OF GASTRIC ULCER

The well known fact that gastric cancer frequently simulates benign gastric ulcer needs re-emphasis.

TABLE 1 Types of Therapy Employed in All Cases of Carcinoma of the Stomach

PERIOD	TOTAL NO OF CASES	NO OPERATION	LAPAROTOMY ONLY	PALLIATIVE OPERATION	RESECTION
		NO OF CASES	NO OF CASES	NO OF CASES	NO OF CASES
1927-1931	296	115	55	58	68
1932-1936	395	135	88	69	103
1937-1941	375	95	73	36	171
1942-1946	457	105	85	22	245

able, if healing is complete, repeat observation should be made one month after discharge from the hospital.

Another method of determining the diagnosis is by means of the cytologic smear, according to Papanicolaou's<sup>7</sup> technic. Fresh gastric washings are precipitated and stained. If malignant cells are found, the diagnosis is almost surely carcinoma. On the other hand, with known cancer of the stomach, the smear will be positive in only about two thirds of the cases. Thus, in the Vincent Memorial laboratory, the results to date have been as follows: in 50 cases of gastric ulcer or cancer in which gastric smears were employed, 24 patients proved to have carcinoma of the stomach, and the smears were positive in 15, of 26 patients without cancer, the smear was reported positive in 1, who proved to have a benign ulcer.<sup>8</sup>

If these recommendations are followed, there will be no significant delay in the recognition of gastric cancers. Furthermore, the very rare case of cancer that will "heal" under the best medical therapy (we have had at least 2 cases in this hospital) will soon be discovered, for the ulceration will recur after the patient leaves the hospital.

That the differential diagnosis of ulcer and cancer is still difficult is attested by the fact that 11 per cent of all the resections in the patients in the present study were made with the preoperative diagnosis of benign gastric ulcer. Fortunately, the delay before operation has been diminished in this group, because it has become appreciated that gastric resection for gastric ulcer produces excellent results, as shown by St. John et al.<sup>9</sup> and Judd and Priestley.<sup>10</sup>

One may ask how many lives might be saved if all the gastric carcinomas in this group were recognized and surgery performed at an early date. Since about 25 patients with apparent gastric ulcer appear in a year in this hospital, of whom about 14 per cent have carcinomas, 3 or 4 patients will be subjected to an earlier resection. Since the five-year curability rate is at least 40 per cent in this group, at least one additional cure a year should be expected in this hospital by early resection. But it is imperative for the surgeon to realize that, even when he has the stomach in his hands, he cannot make the differential diagnosis between ulcer and cancer, and that he must carry out the proper operation for gastric cancer.

#### EXTENSION OF THE OPERATIVE PROCEDURE

Gastric resection for carcinoma originally involved no attempt to excise any tissue but that of the stomach itself. However, the importance of removal of the regional lymph nodes along the lesser and greater curvatures was soon recognized, since the earliest metastases are usually found there. A second feature was emphasized by Castleman,<sup>11</sup> who showed the frequency of invasion of the proximal centimeter of duodenum by cancer of the stomach; he found that extension rarely proceeded beyond this level. A third site of early extension pointed out by Ogilvie<sup>12</sup> and Allen<sup>13</sup> is the great omentum. Metastases there are not uncommon, and may be overlooked except on microscopic section.

These three areas — the regional lymph nodes, the proximal centimeter of duodenum and the great omentum — should be removed with every resection for cancer of the stomach in which cure is the objective. Of course, if disease is to be left behind in other spots inaccessible to surgical removal, and only a palliative resection is planned, there is no need to remove the omentum in every case, although it is usually better to do so. After a long experience with this procedure, we are convinced that it carries no hazard and may contribute to a smoother convalescence.

As a corollary to the concept that gastric ulcer should be considered to be cancer until the pathologist proves it to be benign, it follows that the same operation should be carried out for gastric ulcer as for gastric cancer — that is, the removal of regional lymph nodes, great omentum and proximal duodenum. There is nothing more distressing to the surgeon than to read the pathologist's report

"carcinoma of the stomach, no lymph nodes are included with the specimen." Yet this happens all too frequently, and many patients who should have the best chances of cure are doomed because of an inadequate operation.

Proximal extension of carcinoma of the stomach to the cardia often requires the procedure of total gastrectomy. This operation, although mentioned in the previous report, was a surgical rarity at that time. The technic as subsequently developed and described by Allen<sup>13</sup> has been followed in this hospital. Since the patients subjected to the procedure usually have extensive tumors, the mortality rate is bound to be high, and the number of cures small. The postoperative life span, however, is often surprisingly long.

The operation of total gastrectomy, in addition to an increased postoperative mortality, has other undesirable features. After operation, it is difficult for many patients to maintain adequate nutrition, and an anemia of significant grade is not uncommon. Studies of patients who have had recurrence after subtotal resections for cancer usually show that metastatic involvement of lymph nodes is present but that the remaining stomach is uninvolved. For these reasons, we do not subscribe to Longmire's<sup>14</sup> theory that all patients with carcinoma of the stomach should be treated by total gastrectomy.

The operative attack on carcinoma of the stomach, has, in the past, been limited by inaccessible proximal extension of the growth into the esophagus and mediastinum. Although it was frequently possible to draw down 3 to 5 cm. of the esophagus and do a total abdominal gastrectomy, in many cases it was impossible to get an adequate margin above the tumor. Recently, Churchill<sup>15</sup> and Sweet,<sup>16</sup> in pioneer work in this hospital, have developed the technic of transthoracic gastrectomy. With this approach through the diaphragm, extension of the cancer into the esophagus is easily amenable to resection.

There are several organs that can be sacrificed, resection en bloc with the carcinoma of the stomach being used. Thus, the transverse colon, the pancreas, the spleen and rarely a local extension into the liver can be resected with the tumor. It is our experience that none of these patients will survive five years, but recurrence of the disease will be delayed.

There are, unfortunately, many areas of metastasis that cannot be removed surgically. Metastatic lymph nodes in the head of the pancreas about the superior mesenteric artery or about the hepatic artery are nearly always nonresectable. Whereas a regional-lymph-node dissection of the left gastric artery may be done, a cure is not to be expected if the nodes about the celiac axis are involved. Metastatic lesions in the liver, if demonstrable, are indicative of widespread involvement of the organ. Removal of visible hepatic metastases will not con-

tribute to the postoperative comfort of the patient or increase the five-year survival rate. Peritoneal metastases are likewise indicative of widespread lymphatic involvement, local removal is useless.

The question might be asked regarding the relative importance of these extensions of the operative procedure so far as the control of cancer of the stomach is concerned. Five-year survivals are not to be expected if other viscera are involved as well as the stomach, so that massive resections of multiple viscera should be considered of value only as palliative procedures. On the other hand, there are rare

continued parenterally several days afterward. Sodium sulfadiazine was employed intravenously for some time before penicillin was available, and is still utilized in some cases. The sulfonamides cannot be used locally with safety, and, as a rule, they may be employed for only a short time because of the danger of renal complications.

Blood replacement has also played an important role. It is essential to remember that a normal red-cell count and hematocrit may be misleading in any given patient, since the blood volume may be low, as Lyons<sup>18</sup> has pointed out. Blood is now given

TABLE 2 Mortality with Various Types of Gastric Resection

TYPE OF OPERATION	NO. OF CASES		OPERATIVE DEATHS		OPERATIVE MORTALITY	
	1937-1941	1942-1946	1937-1941	1942-1946	1937-1941 %	1942-1946 %

Averages					26	11

five-year survivals after total gastrectomy. Obviously, the transthoracic approach has opened a new field that cannot yet be appraised accurately.

#### REDUCTION OF POSTOPERATIVE MORTALITY

The method of increasing the number of five-year cures of cancer of the stomach that has heretofore seemed to offer the most promise has been the reduction of excessive postoperative mortality. Thus, in the period 1932 to 1936, the mortality of gastric resection for cancer was 25 per cent. If these patients had not died, the five-year cures following resection would have increased by the same percentage.

It is gratifying to note that the mortality of resections has declined appreciably in recent years. The factors that have contributed are chiefly improved anesthesia, more careful blood, protein and vitamin replacement and chemotherapy. The anesthetic agent now employed is most commonly ether, by intratracheal administration, although our choice in patients who are not to have the diaphragm opened is continuous novocain administered in the spinal area by the method of Arrowood and Foldes.<sup>17</sup>

Local and parenteral use of penicillin just before, during and after operation has contributed a great deal to a smooth convalescence. Especially in transthoracic approaches, Sweet<sup>16</sup> has found that the use of penicillin has practically eliminated the complication of empyema. It appears to be no less effective in the peritoneal cavity. For full effect, it should be started before operation and

very liberally, therefore, despite normal laboratory figures. Likewise, intravenous amigen or amino acids and vitamins are administered in large doses when indicated preoperatively and as a routine measure postoperatively.

A technical contribution of great importance is that of Allen and Donaldson,<sup>19</sup> who introduced the routine use of double jejunostomy after gastric resections. The proximal tube is led back through the gastroenterostomy, and the distal one serves as a jejunostomy for feeding. Thus, the stomach is decompressed postoperatively without the use of a Levine tube. Stomal obstruction, which occurred in about 1 out of 20 patients in the series of Allen and Welch,<sup>20</sup> is no longer to be feared as a complication.

Although pulmonary emboli have not been eliminated as a cause of death, they have been reduced in number in recent years by prophylactic ligation of the superficial femoral veins, by the method of Allen, Linton and Donaldson.<sup>21</sup> We believe that this procedure is indicated in any patient who has a curable lesion, preferably at the time of resection, or within forty-eight hours thereafter.

These advances in therapy have resulted in a definite decrease in the number of postoperative deaths. Table 2 and Figure 2 show that the percentage of postoperative deaths has consistently diminished although the operability has increased.

To determine the effect of postoperative mortality on the curability rate, it is necessary to divide the resections into various groups (Table 2). Subtotal resections "for cure" represent cases in which the

surgeon has removed all gross cancer from the abdomen, and is the group that actually contains nearly all the cured patients. "Palliative" subtotal resections include cases in which cancer is left behind in inaccessible areas at the time of resection, no cures are to be expected. With total gastrectomies five-year cures are very rare, whereas trans-thoracic gastrectomies have not been done long enough to evaluate the curability rate. Hence, only subtotal resections for cure need be considered

FIGURE 2. Prognosis in Cancer of the Stomach  
The fate of all patients entering the hospital with this diagnosis is demonstrated by decades

The postoperative mortality in this group was 11 per cent in 1937 to 1941, and 3 per cent from 1942 to 1946. This means that the factor of postoperative mortality can, at present, no longer be reduced significantly, and that other methods must be found to increase the number of cures.

#### FIVE-YEAR SURVIVALS

What, then, is the ultimate fate of the patient who enters the hospital with carcinoma of the stomach? A graphic summary, comparing the results of the present decade with those of the last, is given in Figure 2, in which the results from 1927 to 1936 are shown by the circled figures. The results in the present series are included in the heavy squares. Incidentally, it may be noted that, in the last five-year series in which it was possible to determine end-result so far as five-year cures are concerned (1937 to 1941), only 4 patients have been untraced. They are considered in the tables to be dead of disease. Several trends are immediately discernible: the number of apparently operable patients has risen from 65 per cent to a level of 75 per cent, the patients who have an operation are much more likely to have a gastrectomy than they were before (50 per cent of all cases, compared with 25 per cent), whereas the percentages of exploratory laparotomies remain about the same and those of palliative operations other than gastrectomy have decreased, in the cases of gastrectomy, there is

little change in the number of hospital deaths, and many more patients live up to four years after operation, and the over-all number of five-year cures has increased from about 5 per cent to 7 per cent.

It is clear that the great increase in the number of gastrectomies is due to the more widespread use of resection as the best palliative operation, even if all gross disease cannot be removed. The increased number of palliative resections has maintained the over-all mortality for resection at the same level as that of the previous study.

A further analysis of the gastrectomies performed is presented in Figure 3. There were no five-year survivals in the patients who had gross disease left in the abdomen, and only a rare five-year survival after total gastrectomy. Practically all the favorable cases fell into the group of subtotal resections, in which all gross cancer is removed.

The statement has sometimes been made that, even if gross cancer is left behind in the abdomen, a cure may result. Our information lends no credence to that claim. Eighty-five per cent of the patients with palliative subtotal gastrectomy were dead a year after operation, and all were dead two years after operation. The average postoperative length of life was about eight months.

Since the average length of life after exploratory laparotomy alone for cancer of the stomach is about six months, palliative gastric resections cannot be defended on the basis that a significant pro-

FIGURE 3. Duration of Life after Various Types of Gastric Resections for Cancer (1937-1941)

longation of life results. On the other hand, patients who have had an obstructing lesion removed are usually more comfortable and may die a relatively painless death from hepatic or pulmonary metastases. Since some patients without hope of cure are condemned to life for a period after operation, such a resection is really palliative. It seems justifiable to continue the use of the term "palliative gastrectomy" to distinguish operations in which gross disease is left behind in the abdomen.

Livingston and Pack<sup>4</sup> have used the term "resectable cancer of the stomach" to describe cases in which all gross cancer can be excised. This is a valuable term, and in the present study is represented by all the subtotal resections, total resections and those done by the transthoracic route in which all gross disease can be removed. In the present series, the mortality for "resectable cancer" is 19 per cent, and the five-year curability is 20 per cent.

The prognosis of any case of carcinoma of the stomach may be gauged fairly accurately by microscopical examination of the specimen. The presence of metastasis to the regional lymph nodes is very

FIGURE 4 Metastasis and Postoperative Duration of Life after Gastric Resection for Cancer

The end-results of all survivals indicate the importance of metastases in the determination of prognosis

grave. Thus, in the years 1937 to 1941, there were 73 operative survivors who had metastases. Only 4 patients, or 5 per cent, lived five years. On the other hand, of the 42 patients who survived operation and had no extension to the regional nodes 20, or about 50 per cent, lived five years (Fig 4).

#### DISCUSSION

Livingston and Pack,<sup>4</sup> in their very complete survey of the treatment and end-results of gastric cancer, present many figures that are interesting to compare with this present series. It must be pointed out that their monograph was published in 1939 and that all clinics have improved their results since then. Thus, Pack<sup>22</sup> has recently reported that the operability in the Memorial Hospital has risen to 50 per cent. Therefore, no special credit need be taken by the Massachusetts General Hospital, except to point out that, here as well as elsewhere, modest gains have been registered in the therapy of cancer of the stomach.

Livingston and Pack state that there is no report in the literature in which the resectability was over 36.4 per cent and that the average rate was 18.7 per cent. Marshall and Welch,<sup>23</sup> in a recent report from the Lahey Clinic, found that 24.1 per cent of all patients with a diagnosis of cancer of the stomach in the years 1936 to 1940 had a resection. Somewhat similar figures were reported by Counsellor<sup>24</sup> from the Mayo Clinic, where resection is carried out in 30 per cent of the patients with a diagnosis of gastric cancer. In our series, 50 per cent had resections, in 16 per cent inaccessible gross disease was left behind, whereas in 34 per cent all gross cancer was excised. The high resectability in this group has contributed to a comparatively high over-all postoperative mortality — 22 per cent. However, during the last five years of the study, although the resectability has increased from 45 to 54 per cent, the postoperative mortality has been reduced to 11 per cent.

Livingston and Pack also found that the average rate of postoperative five-year survivals from surgical treatment in the clinics studied was less than 2 per cent of the patients observed, the best rate reported from any surgical clinic or cancer center has never exceeded 5.2 per cent. In this series, from the years 1937 to 1941 (the last period available for end-results), there were 7 per cent five-year survivals.\*

#### SUMMARY

A study of all the patients with carcinoma of the stomach admitted to the Massachusetts General Hospital during the ten-year period 1937 to 1946 shows that the delay before treatment has remained unchanged, averaging five months. A more aggressive attitude toward gastric ulcer has increased the recognition of early cancer of the stomach.

The introduction of a transthoracic approach and the wider use of total abdominal gastrectomy have increased the number of cases available for resection.

The mortality for gastric resections for cancer has dropped to a present level of 17 per cent for the entire series and to 11 per cent in the last five-year period. The mortality of subtotal resections in which all gross disease is removed has been 3 per cent in the last five-year period.

Meanwhile, the number of unoperated patients has declined so that 75 per cent have an operation. Fifty per cent of the total have a gastrectomy, either subtotal or total.

The best palliative operation, if gross disease cannot be removed, is subtotal gastrectomy.

The five-year survival rate is now 7 per cent of the entire group that enters the hospital.

The most fruitful method now available to increase the number of cures of cancer of the stomach

\*Since this article was submitted for publication, State, Moore and Wangenstein<sup>25</sup> have surveyed the patients with carcinoma of the stomach entering the University of Minnesota Hospital from 1936 to 1945. Their figures show a 55.2 per cent resectability, with a mortality of 16.6 per cent, and an over all five-year salvage of 6.6 per cent.

is to reduce the delay from onset of symptoms to surgical intervention

## COMPLETE HEART BLOCK\*

### A Study of Two Cases in Veterans of World War II

CHARLES FISCH, M.D.

INDIANAPOLIS, INDIANA

A NUMBER of reports in the medical literature emphasize the fact that some patients with complete heart block may have a favorable prognosis regarding life and the ability to perform daily tasks. In nearly every case the conduction defect is thought to be congenital in origin. Campbell,<sup>1</sup> in his discussion of congenital complete heart block, states that, "if there are no complications carrying special risks of their own, the prognosis is good and will probably prove that the condition is compatible with survival to old age." The cases reported below emphasize the ability of people affected with this malady to lead normal lives and at times to undergo rather strenuous exertion without demonstrable ill effects. Both patients were veterans of World War II. Only 1 case is reported in the literature in which a patient with complete heart block, apparently congenital in origin, was a member of the armed forces.<sup>1</sup>

## CASE REPORTS

**CASE 1** A 34-year-old man reported to the Out Patient Department on June 11, 1947, for compensation examination because of complete heart block. He had been inducted into the service on December 7, 1943. Preinduction physical examination had revealed a resting pulse rate of 34

rising to 80 on exercise. The remaining examination revealed no abnormalities. After induction he completed 8 weeks of basic training. During a routine screening examination a systolic apical murmur was heard and the patient

FIGURE 1. Tracing Obtained in Case 1 on May 15, 1943, Showing Complete Atrioventricular Dissociation with an Atrial Rate between 53 and 60 and a Ventricular Rate of 43. The T waves are upright in Lead I, diphasic in Lead 2 and inverted in Lead 3. The T waves in Lead IV are upright.

was hospitalized for observation. An electrocardiogram taken on May 15 had shown complete heart block with a diphasic T wave in Lead 1, inverted T waves in Leads 2 and 3 and an upright T wave in Lead 4 (Fig. 1). No other

†Resident in medicine, Veterans Administration Hospital.

significant abnormality had been demonstrated during the study. The patient had been discharged from the service on June 5 and had subsequently been employed as a night clerk in a hotel, where he performed general manual labor.

The past history revealed a normal birth after a normal period of gestation. As a child the patient had measles, mumps, chicken pox and pertussis. At the age of 23, while playing baseball, he suddenly fainted. Since that time he had experienced six similar episodes, the last occurring at the age of 28 years. Additional medical history revealed that when the patient was 25 years old he had been told that he had a "bad heart." There was no history of scarlet fever, rheumatic fever, tuberculosis, syphilis or diabetes. The patient had attended school until he was 13 years old. At that time he completed the sixth grade, he incurred no difficulty in learning, but his schooling was stopped owing to the death of his father, whose position as a bread winner the patient accepted. At first he worked as a farm hand and later as a

Fluoroscopic examination of the heart showed the cardiac silhouette to be normal in size and shape.

An electrocardiogram revealed a complete heart block, with a diphasic T wave in Lead I and inverted T waves in Leads 2, 3 and F<sub>4</sub> (Fig. 2).

**CASE 2** A 19-year-old veteran reported to the Out-Patient Department for treatment because of "heart trouble" and "weakness."

The patient had been a premature baby and had supposedly weighed only 3 pounds at birth. A further developmental history did not reveal anything unusual. The patient had had measles, mumps, whooping cough and chicken pox. After the period of childhood, except for occasional sore throat, he had never been sick. There was no history of scarlet fever, rheumatic fever, tuberculosis, diphtheria or syphilis. He gave a history of two syncopal attacks, both occurring at the pre-school age. No details concerning these episodes

FIGURE 2 *Electrocardiogram Obtained in Case 1 on June 11, 1947, Showing Complete Heart Block. Note the T-wave changes that have taken place since the last observation.*

laborer on a railroad. He also held a job in a canning factory and finally was employed as a guard in a defense plant. He had no difficulty performing any of these tasks.

The family history was irrelevant.

Physical examination revealed a well developed and well nourished man who appeared to be in excellent health. The height was 69 inches, and the weight 175 pounds. An exercise-tolerance test, consisting of stepping on and off a chair 18 inches high twenty-five times, caused only a mild dyspnea. Examination of the heart showed no enlargement. There was a Grade I, blowing, systolic apical murmur transmitted only slightly toward the sternum. The murmur was somewhat accentuated by exercise. The remainder of the physical examination disclosed nothing of note.

The blood pressure was 120/80. The resting pulse was 52, rising to 80 after exercise.

Examination of the blood disclosed a red-cell count of 4,450,000 and a white-cell count of 6000, with 66 per cent neutrophils and 34 per cent lymphocytes. The sedimentation rate was 1 mm in 1 hour.

were obtainable. While in school he had no difficulty keeping up with other children. He was a member of the high-school basketball team. After completing 2 years of high-school education, he went to work for a packing company. This called for arduous manual labor, which he was able to perform without any ill effects. His next job was that of a truck driver. He subsequently passed a physical examination for a Civil Service position, which he held until his enlistment in the United States Navy on January 5, 1945. Physical examination performed prior to enlistment showed a pulse rate of 48, which increased to 56 with exercise. The remainder of the examination was reported as showing nothing of note. The patient was accepted for duty with the Navy and had no difficulty until April 25, 1945, when he reported to sick bay because of an upper respiratory infection. At the time of admission to the hospital the pulse rate was 44, "increasing only slightly with exercise." A diagnosis of complete heart block was made, the diagnosis being confirmed by a number of electrocardiographic tracings. The patient was discharged from the service on July 10 and subsequently re-

turned to his old job that of a truck driver. He was unable to perform his duties as well as he did before he entered the Navy because, as he put it, "he felt weak all over."

The family history was of no consequence.

Physical examination disclosed a patient of hyposthenic habits. He did not appear either acutely or chronically ill. An exercise tolerance test consisting of stepping on and off a chair 18 inches high revealed only a mild dyspnea. Examination of the heart disclosed some enlargement to the left, the left border of cardiac dullness being slightly outside the midclavicular line. No thrills were palpable either

rate as compared with acquired complete heart block. The study of the 2 subjects revealed some evidence that may justifiably be construed as indicative of disease of the heart other than the conduction defect. In Case 1 there was an associated progressive inversion of the T waves in Leads 1, 2, 3 and F<sub>4</sub>. This may have been due to some obscure pathologic process, possibly infectious in origin, in-

FIGURE 3. *Electrocardiogram in Case 2 Showing Complete Heart Block with an Atrial Rate of Approximately 60 and a 1:1 Ventricular Rate of 33.3. No other significant abnormalities are noted.*

before or after exercise. There was a Grade II blowing systolic murmur, which was best heard in the third and fourth interspaces just to the left of the sternum. This murmur was transmitted toward the apex and was somewhat accentuated by exercise. The remainder of the examination was negative.

The pulse rate was 40, regularly increasing to 52 with exercise. The blood pressure was 140/70.

Fluoroscope examination showed a mild enlargement of both the right and left ventricles.

An electrocardiogram revealed a complete heart block (Fig. 3).

### DISCUSSION

It is true that the etiology of the heart block in the cases reported above is open to question. However, the following findings strongly suggested the congenital origin of the conduction defect: the absence of an acquired etiologic agent that is known to affect the myocardium, the ability of the patients to lead normal lives and at times to undergo rather strenuous exertion without demonstrable ill effects, and the presence of a relatively faster pulse

volving the myocardium or the pericardium, or both, or to a process involving the coronary arteries. No definite conclusion can be reached at present. In Case 2 the systolic murmur coupled with the enlargement of the heart might perhaps be ascribed to the increased stroke volume associated with the slow heart rate.

A review of the literature regarding congenital complete heart block showed a lack of uniform criteria to which a case must conform before it may be assumed to be congenital in origin. Yater,<sup>2</sup> in a review of this subject in 1929, pointed out certain requirements that should be fulfilled before a diagnosis of congenital complete heart block can be made. These are as follows: electrocardiographic proof of heart block, a record of a slow pulse at an early age, and absence of a history of infection, especially diphtheria, rheumatic fever, chorea or congenital syphilis. He also stated that syncopal

attacks at a fairly early age and the presence of other congenital heart lesions add weight to the congenital etiology of the heart block. Most writers assume that complete heart block in children and young adults is to be considered infectious in origin until proved otherwise. Recently, different ideas were expressed.<sup>1, 3</sup> Leys<sup>4</sup> points out that permanent complete heart block following infection is rare and also states that the burden of proof lies on the shoulders of the one who assumes that a case of complete heart block in young adults is due to infection. White<sup>5</sup> asserts that permanent heart block following an acute infectious process is rare and that the most frequent cause of complete heart block is coronary-artery disease. Campbell,<sup>6</sup> in a review of 64 cases of complete heart block, found that 13 per cent were congenital in origin, and slightly over 10 per cent could be accounted for by syphilis and rheumatic fever. Seventy-five per cent of the cases were due to coronary-artery disease.

Subjective complaints caused by congenital complete heart block are few. A small percentage of the patients experience Stokes-Adams attacks or shortness of breath, or both, on moderate exertion. Others develop neurasthenia after learning about their malady.

Yater<sup>2</sup> calls attention to the relative infrequency of cyanosis in these patients. When cyanosis is found, it is probably due to an accompanying heart lesion rather than to the heart block per se. Physical examination usually reveals a pulse rate of 40 to 50 and an enlarged heart. This cardiac enlargement may be attributed to an associated heart lesion or to prolonged diastolic filling due to slow heart rate.

It is of great practical importance to differentiate congenital complete heart block from the acquired condition, for the prognosis for life and the capacity to lead normal lives is good in congenital heart block. In a series of 8 cases that Campbell<sup>1</sup> followed for nine years he reported 2 deaths. The average sur-

vival rate for the other 6 patients was twenty-two years on last examination. The ages of these patients ranged from twenty-two to forty-two years. Jaleski and Morrison<sup>7</sup> reported a case in a thirty-one-year-old woman with congenital complete heart block who went through two terms of pregnancy and delivery without any complications. Levine<sup>8</sup> mentions a fifty-five-year-old patient who was known to have had complete heart block since the age of six, probably of congenital origin. The optimistic outlook in congenital complete heart block mentioned above should be contrasted with life expectancy in acquired heart block. The studies of Campbell<sup>6</sup> and Graybiel and White<sup>9</sup> show that approximately 70 per cent of patients with acquired heart block died less than three years after the discovery of the lesion. The remaining 30 per cent were alive after an average of six to seven years.

### SUMMARY

Two cases of complete heart block, probably congenital in origin, in veterans of World War II are presented.

The significant clinical aspects of congenital complete heart block are discussed.

## VACCINATION AGAINST INFLUENZA A AND B\*

## A Comparison of Reactions, Doses and Titer Responses of Two Different Vaccines in Infants and Children

R I LIENKE, M.D.,† E PERRY CRUMP, M.D.,‡ AND JOHN M ADAMS, M.D.§

MINNEAPOLIS, MINNESOTA

ALTHOUGH numerous investigators have reported success in protecting adults from influenza A and B, very few studies are available in infants and children. A quantitative evaluation of the titer responses in this age group to various doses and types of vaccines was undertaken, as well as a study of the local and systemic reactions

## METHOD

The inoculations of vaccine were given subcutaneously from 9 to 10 a m. Temperatures were taken at four-hour intervals, and changes were computed by comparison with the patient's previous temperature record. The maximum rise was

TABLE 1 Temperature Elevations

to the vaccines. Adams, Thigpen and Richard<sup>1</sup> showed that the immune response to influenza A infection was equally great in young infants and older children.

A group of 245 children, ranging in age from one to sixteen years and interned in one building for residua of poliomyelitis, were the subjects of this study. The children were divided into five groups, all of which were nearly comparable in age distribution. The first two groups received 0.5-cc and 1-cc doses of vaccine 1 ¶. The second two groups received the same doses of vaccine 2 ||. The fifth group was not vaccinated, but early and later serum titer studies were done as in the first four groups. This study was carried out in November and December, 1946.

determined in each of 186 cases, as well as the mean maximum for each group.

The local reaction was evaluated immediately, and at intervals of approximately twenty-four hours for thirty days.

Samples of blood were obtained before the vaccine was given and fourteen days after its administration. The viruses used in the quantitative titer determinations were those of influenza A (PR 8 strain) and influenza B (Lee strain). The photoelectric densitometer was employed after the method described by Hirst and Pickels.<sup>2</sup> All the four hundred and fifty-six determinations were done in pairs and in large lots.

## RESULTS

## Temperature

The means of the maximum temperature elevations are presented in Table 1. The values show that 0.5 cc of a vaccine gave the same average temperature rise as 1 cc of the same vaccine. Vaccine 1 caused a significantly higher temperature response than vaccine 2. Many children receiving the former had temperatures well over 100°F. The maximum temperature elevation occurred most frequently eight to twelve hours after vaccination.

## Local Reaction

The injection of vaccine 1 caused a sharp, stinging pain, which lasted a few minutes and then subsided.

\*From the Department of Pediatrics of the University of Minnesota Medical School.

‡Teschling fellow, Department of Pediatrics, University of Minnesota Medical School.

¶Professor of pediatrics, Meharry Medical College, Nashville, Tennessee, senior fellow of the National Research Council, on leave from Meharry Medical College.

||Associate professor of pediatrics, University of Minnesota Medical School.

¶This vaccine, which was prepared from egg cultures of influenza A (PR 8 and Weiss strains) and B (Lee strain) viruses by erythrocyte adsorption and elution, was kindly supplied by Eli Lilly and Company, Indianapolis, Indiana.

||This vaccine, which was prepared from egg cultures of influenza A (PR 8 and Weiss strains) and B (Lee strain) viruses by calcium phosphate adsorption, was kindly supplied by Parke Davis and Company, Detroit, Michigan.

Vaccine 2 caused little or no immediate pain. The local reaction was measured and palpated at intervals, and although there was considerable variation, the following general observations were made twenty-four hours after the injection of vaccine 1: there was a small area (1 or 2 cm.) of erythema,

TABLE 2 Frequency of Systemic Reactions to Influenza Vaccine

VACCINE	DOSE cc	TOTAL NO OF SUBJECTS	SUBJECTS WITH REACTIONS	
			NO	PERCENTAGE
1	0.5	39	11	28
2	0.5	48	3	6
1	1.0	49	10	20
2	1.0	48	8	17

which was slightly swollen and indurated and moderately tender. At forty-eight hours there was usually minimal or no local reaction remaining. Twenty-four hours after the administration of vaccine 2 there was an area of erythema, which, on the average, was significantly larger (2 to 10 cm.) than that caused by vaccine 1. Also, the local site was usually more swollen and indurated, and in a

quent, reactions were observed with vaccine 1. The least number of systemic reactions occurred with 0.5 cc. of vaccine 2. A convulsion occurred in a one-year-old girl who received 1 cc. of vaccine 1.

No unquestionably positive reaction was observed in any of the 60 children who were given skin tests. Difficulty in interpreting skin tests with the undiluted vaccine was encountered because of the irritative properties of the formalin contained in the material used. (None of these subjects are included in the titer studies.) Curphey<sup>3</sup> has reported a fatal allergic reaction to influenza vaccine. Ratner and Untracht<sup>4</sup> cited several allergic reactions and recommend that all patients be tested with 0.02 cc. of the undiluted vaccine before vaccination. Protamine-precipitated vaccine,<sup>5</sup> like that of calcium phosphate adsorbed, apparently contains less allergenic substance than the vaccine prepared by erythrocyte adsorption. A newer vaccine prepared by centrifugation<sup>6</sup> is said to be virtually free of substances causing allergic reactions.

Antibody Titers

The increase in the antibody titer is indicated by the ratio of the late to the early value rather than

TABLE 3 Frequency Distribution of Titer Ratios

VACCINE	DOSE cc	INFLUENZA VIRUS	SUBJECTS WITH INCREASE OF LATE OVER EARLY TITER				TOTAL NO OF TITER PAIRS	GEOMETRIC MEANS OF INCREASES
			LESS THAN 2 FOLD	2 TO 3 FOLD	4 TO 7 FOLD	8 TO 50 FOLD		
1	0.5	A	14	3*	7	3	27*	2.4 fold
2	0.5	A	14	5	1	2	22	3.5 fold
1	0.5	B	8	8	6	5	27	1.9 fold
2	0.5	B	9	7	2	4	22	2.9 fold
1	1.0	A	11	7	3	1	22	2.1 fold
2	1.0	A	5	3	4	2	14	4.1 fold
1	1.0	B	4	6	6	5	21	3.0 fold
2	1.0	B	1	2	3	7	13	7.8 fold
(Control)		A	30	0	0	0	30	1.0 fold
(Control)		B	30	0	0	0	30	1.0 fold†

\*Of the 27 titer pairs against influenza A in the group receiving 0.5 cc. of vaccine 1, there were 3 with late titers showing an increased range of 2 to 3.9 fold over the early titers.  
†1.0 fold represents no increase in the late over the early titer.

few subjects the whole upper arm was tender. At the end of forty-eight hours a definite subcutaneous nodule had formed in most of the subjects receiving vaccine 2. This was still present thirty days later in a few cases.

Systemic Reactions

The number of systemic reactions is recorded in Table 2. The ages of the children with reactions ranged from thirteen months to nine years in the group given 0.5 cc. of vaccine 1, three to thirteen years in the group given 0.5 cc. of vaccine 2, sixteen months to sixteen years in the group given 1 cc. of vaccine 1 and two to fifteen years in the group given 1 cc. of vaccine 2. The principal reactions were headache, restlessness and wakefulness. In general it was concluded that severer, as well as more fre-

quent, reactions were observed with vaccine 1. The frequency distribution of all the cases in terms of the number of fold increase of the late titer over the early titer (late to early ratio)

In view of the fact that the titers increase in a geometric fashion, the geometric mean was employed in the group comparisons, and the statistical calculations were made on the basis of logarithms. The geometric means for the titer increases are included in Table 3. All the means in the groups receiving vaccine were significantly higher than those in the control group. Except for the mean increase of 7.84 against the virus of influenza B in the group receiving 1 cc. of vaccine 2, in which the number of patients was too small and the range of values too great to justify an accurate comparison, there was no significant difference

between the groups. For example, 1 cc of a vaccine was no better than 0.5 cc of the same vaccine, nor was vaccine 1 better than vaccine 2 from this point of view. There did not appear to be any differences in the titer response of the younger compared to the older children. The titers against the virus of influenza B were generally higher than those against the virus of influenza A.

### DISCUSSION

The subjects in our study were not exposed to an epidemic of influenza, so that the value of the vaccinations was not tested clinically. A fairly consistent rise in antibody titers was demonstrated in the majority of the vaccinated group as opposed to the controls. Henle, Henle and Stokes<sup>7</sup> have shown greater protection against the disease in the persons with the high titers. The majority of the subjects whose titers failed to rise appreciably (less than twofold) had high initial levels.

All the inoculations were given subcutaneously. Van Gelder and his associates<sup>8</sup> concluded that the intracutaneous route produced better titer responses. No subject in our study received more than one injection. The antibody level reached after one dose was as high as that observed after two doses according to a study reported by Hare and his co-workers.<sup>9</sup>

The second blood sample was drawn after fourteen days in all subjects. These titers probably did not represent the maximum level in each case because of varying host responses as well as the differences in vaccines used.

In our experience, the vaccines employed were safe for infants and children in the doses employed, and with one exception, in which a large dose was given to a one-year-old child, no severe reactions were observed in the 245 subjects. The question of the use of influenza vaccine in the practice of medicine remains for the individual physician to answer. Certainly, it may be offered as giving protection of some degree to most persons, since its value has now been attested by several reports, including that of the Army Influenza Commission.<sup>10</sup> The administration of any vaccine entails an occasional unfavorable reaction. Whether or not this militates against its use in practice cannot be decided here, but its value as a public-health measure can hardly be questioned when the morbidity and mortality figures in large cities after influenza epidemics are studied. The uncomplicated disease except for pandemics probably is not responsible for death, but it is one of the common precursors of

pneumonia, which takes its toll after every influenza epidemic. The pandemics of influenza recorded in medical history have been responsible for more deaths than any scourge known to man. One of the probable causes of pandemics is a world-wide susceptibility. It seems possible that extensive use of influenza A and B vaccine will offer man some protection against pandemic as well as epidemic influenza and against the high mortality associated with this disease.

### SUMMARY

A comparative study of reactions, doses and antibody titers has been made with two different vaccines against influenza A and B in infants and children.

The temperature elevations were significantly higher with vaccine 1 than with vaccine 2, although the dose of the vaccines did not appear to make any appreciable difference. Vaccine 2 caused more local reactions, such as swelling and tenderness at the site of inoculation, whereas the systemic reactions appeared to be more intense with vaccine 1.

A definite increase in the antibody titers was demonstrated in the majority of the vaccinated subjects as compared to the controls, but no significant difference between the vaccines was observed.

There was no significant difference between the titers obtained with 0.5 cc and 1 cc of the same vaccine. Children under three years of age, in our opinion, should not be given more than 0.5 cc of vaccine.

The decision whether or not to use influenza vaccine is left to the individual physician.

ACUTE MENINGITIS CAUSED BY *NEISSERIA SICCA*\*

CHARLOTTE BANSMER, M.D.,† AND JACOB BREM, M.D.‡

NEW ROCHELLE, NEW YORK, AND WORCESTER, MASSACHUSETTS

THE gram-negative diplococci such as *Neisseria catarrhalis* and *N. sicca*, commonly found in the pharynx, rarely cause meningitis. However, upon occasions they have been proved to be the sole cause of the disease.<sup>1-10</sup> The following case of meningitis due to *N. sicca* was proved by culture and serologic examination §

R. L., a 6½-year-old boy, entered the hospital on January 20, 1947, with a history of sore throat, frontal headache, fever and vomiting of 24 hours' duration. The temperature had risen to 104°F, the headache had increased in severity and he had developed a stiff neck a few hours before admission. The patient had received several doses of sulfadiazine at home, but most of this had been lost in the vomitus.

The past and family histories were noncontributory except for left internal strabismus since infancy.

Physical examination revealed a well developed and well nourished child, who was drowsy but conscious and cooperative. There were no abnormal eye findings except for the left internal strabismus. The fundi were normal. Definite spinal and nuchal rigidity were elicited. The mucous membrane of the throat was somewhat inflamed. The ears were normal. The posterior cervical lymph nodes were slightly enlarged. No petechiae were noted. A bilateral Kernig reflex was present. The blood pressure was 100/70.

Examination of the blood showed a red-cell count of 3,930,000 and a white-cell count of 15,200, with 86 per cent neutrophils, 12 per cent lymphocytes and 2 per cent eosinophils. A blood culture was negative, as was a tuberculin patch test. An x-ray film of the chest was normal. The blood sulfadiazine level ranged from 9 to 15 mg per 100 cc. A lumbar puncture was done and 10 cc of cloudy spinal fluid, under increased pressure, was obtained. The initial pressure was equivalent to 280 mm of water, the dynamics were normal. Examination of the spinal fluid disclosed a white-cell count of 4150, with 84 per cent polymorphonuclear leukocytes, 16 per cent lymphocytes and a total protein of 80 mg, sugar of 83 mg and chloride of 720 mg per 100 cc. A direct smear demonstrated many pus cells but no organisms, a culture showed *N. sicca*.

As soon as the diagnosis of meningitis had been established the patient was given sodium sulfadiazine intravenously and penicillin intramuscularly. Because the previous vomiting had resulted in some dehydration, 5 per cent glucose in physiologic saline solution with 1/6 molar lactate was given intravenously. In the evening of the 2nd hospital day, the urine was noted to be grossly bloody, and sodium sulfadiazine was therefore discontinued. Streptomycin (125,000 units every 3 hours) was started, and 1/6 molar lactate was continued intravenously to keep the urine alkaline — 24 hours later the urine was free of blood.

On the day after admission the patient showed considerable improvement, and he was able to retain food. Penicillin was given intrathecally (5000 units in 5 cc of physiologic saline solution) on the 2nd and 3rd days. The urine contained red cells on the 3rd hospital day but was normal thereafter. On the 4th hospital day, there were no clinical signs of meningitis. Streptomycin was discontinued, and at that time oral glucosulfadiazine was given without any further untoward effect. The patient continued to improve. Penicillin was discontinued on the 9th, and glucosulfadiazine on the 11th hospital day. The spinal fluid on discharge was

clear, with 4 white cells per cubic millimeter, 100 per cent lymphocytes, a sugar of 49 mg per 100 cc and a total protein of 36 mg per 100 cc, culture was negative.

Serum agglutination with *N. sicca* demonstrated a positive titer in a dilution of 1:384 (control, negative) 12 days and one of 1:384 (control 1:96) 61 days after the onset of the acute illness. The titer was negative for both patient and control 154 days after the onset.

## DISCUSSION

The initial diagnosis in this case was meningococcal meningitis, in view of the presence of clinical meningitis with cloudy spinal fluid, which on direct smear showed many pus cells but no organisms. The diagnosis was further strengthened by the report of the presence of a gram-negative diplococcus obtained from the culture of the spinal fluid. However, the laboratory soon reported that the organism isolated did not agglutinate with any of the strains of meningococci available. Subsequently, this organism was identified by the laboratory of the Worcester Public Health Department and confirmed by the laboratory of the Massachusetts Department of Public Health as *N. sicca*.

The possibility of contamination of the spinal fluid was entertained, but on inquiry it was found that this organism is a very rare contaminant.<sup>11</sup>

The question of determining whether the patient had developed immune bodies to this organism was then investigated. Because *N. sicca* tends to clump spontaneously in the presence of physiologic saline solution, the antigen was prepared by a special method to minimize this phenomenon. The organism was grown on nutrient agar slants and incubated at 35°C for forty-eight hours. The slants were washed off with tap water as a precautionary measure to avoid automatic precipitation of the organism. The harvest was collected and ground up with fine sand,<sup>12</sup> and the suspension was allowed to stand for one hour. The supernatant fluid was decanted through cotton, and the suspension diluted with tap water to a No. 8 McFarland nephelometer standard of approximately 2,400,000,000 organisms per cubic centimeter. The antigen was then killed at 60°C for one hour. No preservative was added. The routine slow macroscopic tube agglutination test was used, as described by Kolmer and Boerner.<sup>12</sup> Inasmuch as there was a small but definitely noticeable amount of antigen precipitation in tap water, a positive reaction was assigned only to tubes that showed marked clearing with the formation of large flakes.

It will be noted that twelve and sixty-one days after the onset of acute symptoms, the organism

§Mr. Philip B. Miner, bacteriologist, Worcester Department of Public Health, carried out the bacteriologic and serologic examinations.

§Suggested by Dr. Raymond H. Goodale, pathologist, Worcester City Hospital.

was agglutinated by the patient's serum in a dilution of 1:384. Approximately five months after the illness the titer had dropped to a normal level. The control serums were presumed to be normal and were obtained from men between the ages of twenty and twenty-three years. The finding of a titer of 1:96 in one of the control serums cannot be definitely explained, except by the fact that the control subject may have had a recent infection with *N. sicca*.

On review of the literature it was found that meningitis due to *N. sicca* has been reported only in the course of an endocarditis caused by this organism.<sup>6-7, 10, 12</sup> In the 5 reported cases of endocarditis, symptoms of meningitis occurred in 3, and a positive spinal-fluid culture was found in 1.<sup>7</sup> All these cases of endocarditis terminated fatally except 1 in which recovery followed the use of heparin and sulfapyridine.<sup>6</sup>

Several cases of meningitis caused by *N. catarrhalis* have been reported<sup>1</sup> and also some cases caused by atypical *Neisseria*.<sup>2, 3, 4, 8, 10</sup> The comparative rarity of meningitis caused by this group of organisms suggests a low pathogenicity but modifies the older concept of this group as non-pathogenic.<sup>14</sup>

#### SUMMARY

A case of acute meningitis caused by *Neisseria sicca* is reported. The organism isolated was identified by two different laboratories. An attempt was made to determine the titer of antibodies in the

patient's serum, cultures of the organism being used as the antigen. Although the serologic method available was not entirely satisfactory because of the characteristics of this organism to clump spontaneously, significant titers indicating antibody formation were obtained. Approximately five months after the onset of the acute disease, the titer had dropped to a normal level.

It is believed that this is the first straightforward case of acute meningitis caused by *N. sicca* and uncomplicated by any other infectious process such as endocarditis described in the literature.

## MEDICAL PROGRESS

### CANCER

GRANTLEY W TAYLOR, M D \*

BOSTON

AS a result of public interest, large sums of money have become available in the field of cancer, from state and federal sources and from charitable foundations, and it seems probable that the interest and funds will continue for a long time. The money has been used for stimulation of research, for cancer education among the laity and the medical profession and for direct service to the patient in the form of improved diagnostic and therapeutic facilities.

#### RESEARCH

The literature of laboratory cancer research has become so voluminous that it is virtually impossible for anyone to undertake to digest it all. The Fourth International Cancer Research Congress presented representative contributions in all the principal fields of investigation. Cowdry's<sup>1</sup> recent summary of the Congress ably recapitulates the major fields of interest.

#### EDUCATION

##### *Undergraduate*

Although a considerable part of a medical-school curriculum deals with cancer, and with basic sciences essential to an understanding of cancer, it is true that in many medical schools there has been little or no attempt to correlate the various components in such a way as to give the student a coherent conception of cancer. A committee of the National Advisory Cancer Council has urged the desirability of co-ordinating the teaching of cancer in medical schools, offering financial support for schools presenting acceptable plans of instruction. Several schools have already adopted the recommendations of the committee, and it is anticipated that others will recognize the merits of the proposals.

##### *Graduate*

Fellowships offered by the National Advisory Cancer Council are intended to train men at the resident level to be cancer specialists. The rather rigid requirements of training in surgery, radiology and pathology make it difficult for many hospitals to fit these fellowships into existing resident training programs. In addition, the fellowships come into conflict with the requirements of many of the specialty certification boards. Some relaxation and

elasticity of the program would probably result in better training of more men.

The American College of Surgeons, at the annual clinical congress and in the sectional meetings, offers special sessions and symposia in cancer. These meetings bring to a large audience a condensed review of recent important advances in the cancer field. The series of special articles appearing in the *Journal of the American Medical Association*,<sup>2</sup> with the co-operation of the American Cancer Society, is designed to bring a concise presentation of cancer subjects to the general practitioner. These articles will be assembled in a book, which will assure their preservation.<sup>3</sup> The announcement of a new journal *Cancer*, under the sponsorship of the American Cancer Society, to include a thorough abstract section in addition to original contributions, is welcome news to all who are working in this field.

##### *Public*

Lay education in cancer has been promoted by various groups, notably by the Women's Field Army of the American Cancer Society. There can be no question that as a result of such education, many patients seek medical advice earlier than they would have done otherwise. They are also likely to require a more thorough examination from their physician. Indeed, the demands of the laity have emphasized the necessity for improved cancer teaching for the profession. The public interest stimulated by lay education has in large measure helped to make available the funds referred to above, and to some degree has given the laity a voice in the projects for which the money is used. The public demand has also been responsible for the development of detection clinics.

#### DETECTION CENTERS

It is a basic postulate that the earlier a cancer is detected and treated, the greater is the likelihood of cure. It is also true that the earliest stages of most cancers give rise to no symptoms. Thus, it would be desirable to have some test to which the apparently healthy person could be submitted that would detect cancer in its earliest stages. The only present test that can be employed is a complete and thorough examination. The more thorough the examination, the greater is the likelihood that cancer will be detected in its early stages. Practical considerations of time, personnel and expense impose

\*Associate in surgery, Harvard Medical School, visiting surgeon, Massachusetts General Hospital, visiting surgeon, Pondville Hospital.

limitations on the thoroughness of the examination. It is apparent that the initial examination must be relatively brief and inexpensive, and that this preliminary screening may be expected to segregate for more extensive study the group most likely to show positive findings.

In regular medical practice the most significant finding on screening is the presence of a symptom or symptoms. Indeed, a patient in general exercises this screening test and consults a physician or goes to a clinic because of a symptom. The physician can then carry out the more thorough investigation necessary to discover the cause of the symptoms. In doing so, he may uncover cancer or some other disease. Without the stimulus of symptoms to be explained, examinations may become perfunctory or routine. Statistics must be available regarding the number of cases of cancer found during the routine physical examinations of applicants for life insurance or of men selected for military service. Statistics are available concerning the expected incidence of cancer in various age groups at a given time.<sup>4</sup>

In response to public pressure, under the sponsorship of various foundations, numerous centers have been established for the detection of cancer. The American College of Surgeons has defined standards for these centers and gives approval to those complying with the standards.<sup>4</sup> Most of the centers report a much higher incidence of cancer than the calculated expected frequency.<sup>4</sup> It is probable that this is due to the inclusion of a large number of persons who are not in fact free from symptoms, and that the centers are serving to this extent as cancer clinics rather than as detection centers.

The centers also reveal a very great number of other conditions requiring medical treatment.<sup>7</sup> These findings may be compared with the number of rejections for physical reasons of men selected for military service. Proponents of the centers consider that many of the nonmalignant conditions encountered are precancerous, and that prompt attention to them prevents the development of cancer. This viewpoint involves a rather broad concept of precancerous conditions.

Although it is premature to evaluate cancer-detection centers, the experiences should be dispassionately reviewed from the standpoint of expense of operation in relation to cases found at a significantly early stage. Follow-up studies of the cases with negative findings should give information regarding the number of cases overlooked. It may well be found that greater numbers of early cancers can be found with less expense of time and money by intensified education of the laity to report early symptoms and of the medical profession to evaluate these early symptoms.

#### DIAGNOSIS

Interest in cytologic methods of diagnosis from smears continues unabated,<sup>8-11</sup> although many

orthodox pathologists preserve a commendable reluctance to accept the findings without reservation.<sup>12</sup> The application of this technic to permit early evaluation of the efficacy of radiation treatment of carcinoma of the cervix, proposed by Graham,<sup>13</sup> may prove to be valuable in the selection of cases requiring surgical intervention. A series of 280 aspiration and punch biopsies was reported by Ellis,<sup>14</sup> with "useful results" in 63 per cent. Meatheringham and Ackerman<sup>15</sup> reported 300 aspiration biopsies on lymph nodes. In 69 aspirations no lymphoid tissue was obtained. A positive diagnosis of carcinoma was made in 147 specimens, and cancer subsequently developed in 32 cases in which the aspiration specimen was negative. Several authors express a warning against aspiration biopsy in possibly operable lung tumors, because of the danger of pleural implantation. Isaacson and Rapoport<sup>16</sup> reported a series of 34 cancer patients who presented an eosinophil count of more than 10 per cent. It is not generally realized that this degree of eosinophilia may be caused by cancer. In 90 per cent of cases multiple metastases were present.

#### LYMPHATIC SPREAD

There has been considerable interest in recent years in amplifying and confirming knowledge of the pathways of lymphatic spread. The brilliant studies of Gilchrist and David<sup>17</sup> on the lymph node metastases of carcinoma of the colon and rectum have greatly influenced the concept of the radical operations for dealing with these cancers. Similar methods of study were employed by Coller, Kay and MacIntyre<sup>18</sup> in cancer of the stomach, colon and rectum. Sweet<sup>19</sup> has contributed to knowledge of the lymphatic spread of carcinoma of the esophagus. Warren and Tompkins<sup>20</sup> have drawn attention to the correlation between prognosis and the numerical extent of lymph-node metastases. Whereas it is generally conceded that lymph-node involvement is usually embolic rather than by permeation, it is evident that the concept of permeation frequently influences the plan of operation, and it remains true that removal of the regional lymphatic vessels en bloc along with the primary focus is an ideal cancer operation when it is feasible.

#### SURGICAL TREATMENT

Critical review of autopsy material discloses that in many cases death from cancer is due to the local extension of the disease, with interference with the functions to adjacent normal organs, rather than to widespread metastatic involvement. Realization of this fact, in conjunction with the general lowering of mortality and morbidity after radical surgery, has led to increasingly radical operative procedures to cope with advanced stages of local disease. Although these operations are too recent to permit evaluation of long-term cures, they offer the possi-

bility of cure in many cases hitherto regarded as inoperable, and in most cases find justification at least as effective palliative procedures. While Brunschwig has written extensively on this subject, the tendency is evident in almost all fields of cancer surgery.

### ORAL CANCER

No single report indicates the trend in the field of oral cancer, but many surgeons are reviving the concept of a one-stage operation for lesions of the tongue, floor of the mouth and cheek, with simultaneous neck dissection and, when necessary, resection of the jaw. These operations can be applied to some cases considered inoperable by conventional standards. Since the procedures are based upon the concept of spread by permeation, which is not the usual method of lymphatic involvement from these cancers, in many cases they show no advantage over the two-stage operations currently practiced. In addition, in coping with inoperable intraoral lesions, they must demonstrate results more satisfactory than those now obtainable by intensive radiation. Although these radical operations undoubtedly have a place, it is likely that their field of employment will be a restricted one.

### CERVICAL-LYMPH-NODE METASTASES

There has been increased willingness on the part of certain surgeons to carry out radical neck dissections bilaterally, with a short interval between the two sides. This procedure involves sacrifice of both internal jugular veins, as well as the anterior and external jugular veins, and is not without danger of causing cerebral damage. In most cases it is probably safer to preserve the internal jugular vein on one side, and it is usually possible to do so. Sugarbaker and Gilford<sup>23</sup> recently drew attention to the combination of neck dissection and jaw resection in cases in which lymph nodes present fixation to the mandible. This procedure has been employed in many clinics, and the dangers of postoperative complications of shock, hemorrhage, sepsis and pneumonia have diminished.

### CARCINOMA OF THE LARYNX

New et al<sup>24</sup> have reported the excellent results obtained by radical surgery in carcinoma of the larynx. Whereas it is true that many of the early cases are amenable to radiation therapy, there is agreement that laryngectomy is the procedure of choice in more advanced cases,<sup>25, 26</sup> and there is evidence that subradical surgical procedures are more effective than radiation in most early cases.

The possibility of training patients in esophageal use of the voice makes laryngectomy more acceptable. Brunschwig<sup>27</sup> has carried out very radical laryngectomy for advanced disease, removing regional lymph nodes and any other structures that may be implicated in the spread of the disease.

### CARCINOMA OF THE LUNG

Most authors recognize the desirability of removing enlarged lymph nodes in the vicinity of the hilus, along with the entire lung, in carcinoma of the lung. In addition surgeons have not hesitated to resect invaded areas of pericardium, parietes or other adherent structures. Although no cures have been obtained by these radical extensions, the operations at least fulfill the desideratum of leaving no obvious disease behind.<sup>28, 29</sup>

There has been increased recognition of the feasibility and desirability of carrying out pulmonary resection for solitary metastasis of sarcomas and carcinomas, and occasionally long-term arrests or even cures are effected.<sup>30</sup>

### CARCINOMA OF THE ESOPHAGUS

The extent of operations for esophageal carcinoma has increased, with better understanding of the intramural and lymphatic spread of the disease. In this field also Brunschwig and Camp<sup>31</sup> have described a very radical extirpation of the total cervical esophagus. Garlock<sup>32</sup> and Sweet<sup>33</sup> have contributed to elucidation of the technical problems of resections.

### CARCINOMA OF THE STOMACH

Coller's<sup>18</sup> studies of metastases have emphasized the desirability of more radical operations for carcinoma of the stomach. Longmire<sup>34</sup> and Wahren<sup>35</sup> have advocated total gastrectomy as a better operation for cancer than subtotal gastrectomy. However, the mortality from total gastrectomy still remains relatively high,<sup>35</sup> and the survivors, even those who are cured of cancer, may be significantly impaired in health.<sup>36</sup> All authors emphasize the urgent need for earlier recognition<sup>37</sup> and for a radical approach to the problem of gastric ulcer.<sup>38, 39</sup>

### MISCELLANEOUS ABDOMINAL CARCINOMAS

In the field of multiple and apparently inoperable abdominal carcinomas, Brunschwig<sup>40, 41</sup> has reported a brilliant series of radical improvisations, as well as modifications of operative technic in carcinomas of the pancreas and duodenum.<sup>42</sup> Resections of the liver for primary carcinoma were reported by Hoyne and Kernohan<sup>43</sup> and by Duckett and Montgomery.<sup>44</sup> Rabinovitch et al<sup>45</sup> described a series of sarcomas of the intestinal tract. Ehrlich and Hunter<sup>46</sup> reviewed the experience of the Army Institute of Pathology in tumors of the gastrointestinal tract.

### CARCINOMA OF THE RECTUM

The same unwillingness to accept local fixation as a contraindication to radical operation applies to carcinoma of the rectum. Bricker<sup>47</sup> presented a number of cases in which parts of the male genitourinary tract were included in the resection, even to the extent of total removal of the bladder,

prostate and vesicles, with transplantation of the ureters into the proximal portion of the bowel. In the female patients it is not unusual to include the uterus and posterior vaginal wall in the resection.

### CARCINOMA OF THE CERVIX

There has been a revival of interest in the radical operation for carcinoma of the cervix,<sup>48</sup> based on the lowered mortality and recognition of the inadequacy of radiation in the control of lymph-node metastases. This operation has also been extended to include certain cases with local invasion of the bladder or rectum or both.<sup>49</sup> The successful outcome of such an operation—total cystectomy, total hysterectomy, lymph-node dissection, abdominoperineal resection of the rectum, vulvectomy, vaginectomy and bilateral ureteral transplantation—is eloquent testimony to improved technology in surgery.

### CARCINOMA OF THE BREAST

Haagensen<sup>49</sup> has returned to the classic Halsted amputation, with wide skin removal, thin skin flaps and routine skin grafts, in the operation for carcinoma of the breast. Most students believe that this elaborate and meticulous operation is not necessary. Differences in results from various clinics are often attributable to differences in the criteria of operability. Ducuing<sup>50</sup> employs a more radical operation than that usually carried out in this country, removing the fascia of the subscapular muscles and the anterior digitations of the serratus magnus muscle and the subclavius muscle, along with the thoracodorsal and long thoracic nerves. Pickrell et al.<sup>51</sup> described techniques employed in localized resections of the thoracic wall in dealing with operative-field recurrences.

### SARCOMA OF THE EXTREMITIES

Gordon-Taylor and Patey<sup>52</sup> presented a further review of their series of interminominoabdominal amputations, chiefly performed for sarcoma of the upper portion of the thigh and pelvis. Pack and Ehrlich<sup>53, 54</sup> have also presented a series of radical amputations, in some cases combined with regional lymph-node dissections, for a variety of advanced malignant conditions. Again on the basis of the theory of lymphatic permeation, Pack et al.<sup>55</sup> stated, "In the lower extremity for primary melanoma of the foot metastatic to inguinal and femoral lymph nodes, we resort to a hip joint disarticulation combined with a retroperitoneal dissection of the iliac and obturator nodes." This procedure appears to be excessively radical unless the authors intended to restrict it to certain cases of advanced disease. Haggart<sup>56</sup> reported a series of radical shoulder-girdle amputations in the treatment of primary malignant tumors of the humerus.

### MALIGNANT LYMPHOMA

Hellwig<sup>57</sup> reported a series of cases of localized malignant lymphoma in which radical surgery was employed, with five-year cures in a significant number of cases.

bility of cure in many cases hitherto regarded as inoperable, and in most cases find justification at least as effective palliative procedures. While Brunschwig has written extensively on this subject, the tendency is evident in almost all fields of cancer surgery.

### ORAL CANCER

No single report indicates the trend in the field of oral cancer, but many surgeons are reviving the concept of a one-stage operation for lesions of the tongue, floor of the mouth and cheek, with simultaneous neck dissection and, when necessary, resection of the jaw. These operations can be applied to some cases considered inoperable by conventional standards. Since the procedures are based upon the concept of spread by permeation, which is not the usual method of lymphatic involvement from these cancers, in many cases they show no advantage over the two-stage operations currently practiced. In addition, in coping with inoperable intraoral lesions, they must demonstrate results more satisfactory than those now obtainable by intensive radiation. Although these radical operations undoubtedly have a place, it is likely that their field of employment will be a restricted one.

### CERVICAL-LYMPH-NODE METASTASES

There has been increased willingness on the part of certain surgeons to carry out radical neck dissections bilaterally, with a short interval between the two sides. This procedure involves sacrifice of both internal jugular veins, as well as the anterior and external jugular veins, and is not without danger of causing cerebral damage. In most cases it is probably safer to preserve the internal jugular vein on one side, and it is usually possible to do so. Sugarbaker and Gilford<sup>23</sup> recently drew attention to the combination of neck dissection and jaw resection in cases in which lymph nodes present fixation to the mandible. This procedure has been employed in many clinics, and the dangers of postoperative complications of shock, hemorrhage, sepsis and pneumonia have diminished.

### CARCINOMA OF THE LARYNX

New et al<sup>24</sup> have reported the excellent results obtained by radical surgery in carcinoma of the larynx. Whereas it is true that many of the early cases are amenable to radiation therapy, there is agreement that laryngectomy is the procedure of choice in more advanced cases,<sup>25, 26</sup> and there is evidence that subradical surgical procedures are more effective than radiation in most early cases.

The possibility of training patients in esophageal use of the voice makes laryngectomy more acceptable. Brunschwig<sup>27</sup> has carried out very radical laryngectomy for advanced disease, removing regional lymph nodes and any other structures that may be implicated in the spread of the disease.

### CARCINOMA OF THE LUNG

Most authors recognize the desirability of removing enlarged lymph nodes in the vicinity of the hilus, along with the entire lung, in carcinoma of the lung. In addition surgeons have not hesitated to resect invaded areas of pericardium, parietes or other adherent structures. Although no cures have been obtained by these radical extensions, the operations at least fulfill the desideratum of leaving no obvious disease behind.<sup>28, 29</sup>

There has been increased recognition of the feasibility and desirability of carrying out pulmonary resection for solitary metastasis of sarcomas and carcinomas, and occasionally long-term arrests or even cures are effected.<sup>30</sup>

### CARCINOMA OF THE ESOPHAGUS

The extent of operations for esophageal carcinoma has increased, with better understanding of the intramural and lymphatic spread of the disease. In this field also Brunschwig and Camp<sup>31</sup> have described a very radical extirpation of the total cervical esophagus. Garlock<sup>32</sup> and Sweet<sup>33</sup> have contributed to elucidation of the technical problems of resections.

### CARCINOMA OF THE STOMACH

Coller's<sup>34</sup> studies of metastases have emphasized the desirability of more radical operations for carcinoma of the stomach. Longmire<sup>35</sup> and Wahren<sup>36</sup> have advocated total gastrectomy as a better operation for cancer than subtotal gastrectomy. However, the mortality from total gastrectomy still remains relatively high,<sup>35</sup> and the survivors, even those who are cured of cancer, may be significantly impaired in health.<sup>36</sup> All authors emphasize the urgent need for earlier recognition<sup>37</sup> and for a radical approach to the problem of gastric ulcer.<sup>38, 39</sup>

### MISCELLANEOUS ABDOMINAL CARCINOMAS

In the field of multiple and apparently inoperable abdominal carcinomas, Brunschwig<sup>40, 41</sup> has reported a brilliant series of radical improvisations, as well as modifications of operative technic in carcinomas of the pancreas and duodenum.<sup>42</sup> Resections of the liver for primary carcinoma were reported by Hoyne and Kernohan<sup>43</sup> and by Duckett and Montgomery.<sup>44</sup> Rabinovitch et al<sup>45</sup> described a series of sarcomas of the intestinal tract. Ehrlich and Hunter<sup>46</sup> reviewed the experience of the Army Institute of Pathology in tumors of the gastrointestinal tract.

### CARCINOMA OF THE RECTUM

The same unwillingness to accept local fixation as a contraindication to radical operation applies to carcinoma of the rectum. Bricker<sup>47</sup> presented a number of cases in which parts of the male genitourinary tract were included in the resection, even to the extent of total removal of the bladder.

prostate and vesicles, with transplantation of the ureters into the proximal portion of the bowel. In the female patients it is not unusual to include the uterus and posterior vaginal wall in the resection.

### CARCINOMA OF THE CERVIX

There has been a revival of interest in the radical operation for carcinoma of the cervix,<sup>48</sup> based on the lowered mortality and recognition of the inadequacy of radiation in the control of lymph-node metastases. This operation has also been extended to include certain cases with local invasion of the bladder or rectum or both.<sup>49</sup> The successful outcome of such an operation—total cystectomy, total hysterectomy, lymph-node dissection, abdominoperineal resection of the rectum, vulvectomy, vaginectomy and bilateral ureteral transplantation—is eloquent testimony to improved technology in surgery.

### CARCINOMA OF THE BREAST

Haagensen<sup>49</sup> has returned to the classic Halsted amputation, with wide skin removal, thin skin flaps and routine skin grafts, in the operation for carcinoma of the breast. Most students believe that this elaborate and meculous operation is not necessary. Differences in results from various clinics are often attributable to differences in the criteria of operability. Ducuing<sup>50</sup> employs a more radical operation than that usually carried out in this country, removing the fascia of the subscapular muscles and the anterior digitations of the serratus magnus muscle and the subclavius muscle, along with the thoracodorsal and long thoracic nerves. Pickrell et al.<sup>51</sup> described techniques employed in localized resections of the thoracic wall in dealing with operative-field recurrences.

### SARCOMA OF THE EXTREMITIES

Gordon-Taylor and Patey<sup>52</sup> presented a further review of their series of interminioabdominal amputations, chiefly performed for sarcoma of the upper portion of the thigh and pelvis. Pack and Ehrlich<sup>53</sup> have also presented a series of radical amputations, in some cases combined with regional lymph-node dissections, for a variety of advanced malignant conditions. Again on the basis of the theory of lymphatic permeation, Pack et al.<sup>54</sup> stated, "In the lower extremity for primary melanoma of the foot metastatic to inguinal and femoral lymph nodes, we resort to a hip joint disarticulation combined with a retroperitoneal dissection of the iliac and obturator nodes." This procedure appears to be excessively radical unless the authors intended to restrict it to certain cases of advanced disease. Haggart<sup>55</sup> reported a series of radical shoulder-girdle amputations in the treatment of primary malignant tumors of the humerus.

### MALIGNANT LYMPHOMA

Hellwig<sup>57</sup> reported a series of cases of localized malignant lymphoma in which radical surgery was employed, with five-year cures in a significant number of cases.

## CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

### Weekly Clinicopathological Exercises

FOUNDED BY RICHARD C CABOT

TRACY B MALLORY, M D, *Editor*

BENJAMIN CASTLEMAN, M D, *Associate Editor*

EDITH E PARRIS, *Assistant Editor*

### CASE 34171

#### PRESENTATION OF CASE

A thirty-year-old man, a store clerk, entered the hospital with a complaint of pain in the stomach.

Six months prior to entry the patient noted a dull, heavy, nonradiating, epigastric pain, which occurred in the morning and after meals. It was relieved in part by alkalies and warm milk. There was no nausea or vomiting and no tarry stools, and only a rare stool contained bright-red blood. There had been no anorexia or weight loss. About a week before admission a dull, constant, nonradiating pain in the left flank suddenly developed. Two days prior to admission there was a dull, aching pain in the hypogastrium. This was intermittent in character and resembled the epigastric pain.

Physical examination showed a well developed and well nourished man who was moderately distressed because of hypogastric pain. The lungs were clear to percussion and auscultation. The heart was not enlarged, and no murmurs were heard. There was tenderness in the abdomen to deep pressure, localized mainly just to the left of the umbilicus. Pressure on that area also produced pain in the

back. There was no rebound tenderness. In addition, there was definite costovertebral-angle tenderness on the left and in the region of the left kidney. The liver and spleen were not palpable. There was thought to be a group of matted lymph nodes at the base of the left jugular vein.

Examination of the blood disclosed a hemoglobin of 13 gm and a white-cell count of 8200, with 77 per cent neutrophils. The urine was normal. A stool specimen gave a negative guaiac reaction. The total protein was 7.4 gm, the nonprotein nitrogen 27 mg per 100 cc, the chloride 98 milliequiv per liter, and the serum amylase 16 units.

On the day of admission a gastrointestinal series revealed a 5-cm filling defect on the greater curvature in the prepyloric region. No ulceration was observed, and peristalsis did not pass through the area. A smear and gastric washings showed no malignant cells. An intravenous pyelogram performed on the third hospital day was not entirely satisfactory because of gas and fecal material in the overlying bowel, but demonstrated a delayed secretion of the dye on the left, with a moderate degree of hydronephrosis and hydroureter. Two days later a retrograde pyelogram again showed a left hydronephrosis and some degree of obstruction to drainage of the opaque medium. On the sixth hospital day a gastroscopy showed the greater curvature to be distorted by red, edematous rugae. There appeared to be spasm over this area, and no peristalsis was present. There was a superficial ulceration on the lesser curvature, which measured 1 mm in depth and 1 cm in diameter. The appearance described extended about halfway up the body of the stomach and then ended rather abruptly. On the eighth hospital day the patient vomited reddish-brown material and had severe, colicky pain in the left flank that persisted.

On the twelfth hospital day an operation was performed.

## DIFFERENTIAL DIAGNOSIS

DR DANIEL S ELLIS It seems to me that it is very clear that this patient had disease involving the stomach and left urinary tract, and I judge that the same disease involved both organs and that it was a malignant process of some kind. I do not know what kind of operation was performed—whether he had a biopsy or whether he was operated on with the idea of attacking the stomach or left urinary tract. Perhaps the x ray films will help in determining the nature of the lesion in the stomach, and also reveal the location of the obstruction in the left urinary tract.

DR STANLEY M WYMAN Examination of the stomach shows the antrum and prepyloric region to be constantly deformed. On the greater curvature there is a constant pressure defect, which elevates the antrum and prepyloric region. The mucosal folds in the lesser and greater curvatures appear unusually thick and prominent. One can see no definite destruction of the mucosa, however. The duodenal loop is not remarkable, but there is deformity of the cap consistent with an old ulcer. The two films from the pyelogram show a slight degree of hydronephrosis on the left with blunting of the minor and major calyces, and widening of the ureter and pelvis. The ureter is traced to the body of the fourth lumbar vertebra. There is no obstruction to that point, and there are no visible stones to account for the dilatation. A single film taken from the retrograde examination shows more clearly the hydronephrosis, which has a generalized character with some delay in the passage of dye at the ureteropelvic junction. No definite obstruction of the ureter can be seen. The kidney outline cannot be adequately detected. The kidney is not displaced in position, and there is no evidence of a pressure defect on the kidney itself. The lung fields and heart are not remarkable.

DR ELLIS Is there any evidence of a soft-tissue mass at the base of the neck?

DR WYMAN No, not in this one film.

DR ELLIS It seems to me that there is no question that if we can ever interpret symptoms as being typical of certain diseases, this patient had a peptic ulcer or ulceration in the stomach, and the original symptom of a dull, nonradiating epigastric pain occurring postprandially early in the morning and relieved by alkalies and warm milk is that of an ulcerating lesion in the stomach. The pain seemed to change very definitely and became hypogastric and related to the region of the left kidney. As far as I am able to determine there are no other clues.

I suppose that a simple peptic ulcer can be fairly well ruled out on the basis that both the gastroscopist and the radiologist who examined the patient thought that there was an extensive lesion involving the lower part of the stomach in the prepyloric

region. Therefore, I believe that this patient had a malignant lesion involving both the stomach and the retroperitoneal lymph nodes and the left ureter, causing hydronephrosis. Such a condition must have been a carcinoma or a lymphoma of some kind. On the law of averages a patient thirty years old ought not to have carcinoma of the stomach, and it is much more likely that he had a lymphoma. The types of lymphomatous disease possibly involving the stomach and the lymph nodes are reticulum-cell sarcoma, lymphosarcoma and, much less likely, Hodgkin's disease. Still another possibility is tuberculosis, of which there seems to be no indication. If this patient's symptoms were first related to the stomach, I think that he had a prepyloric lesion, which was primary in the stomach and metastasized, involving the left urinary tract, causing pressure on the left ureter, with secondary hydronephrosis, and I shall put lymphosarcoma as the first choice. Having had two cases of renal-cell carcinoma before me today, I suppose I am on the spot to say that this is a third case of renal-cell carcinoma, since things usually come in threes. I think that a primary renal tumor with metastases involving the stomach would be less likely than the other way around—that this was a primary carcinoma of the stomach with metastases involving the left urinary tract. I do not believe that this was a scirrhus type of cancer such as one sees in *linitis plastica*, although it was certainly an infiltrating lesion from the description.

I shall conclude by saying that this man had lymphosarcoma, primary in the stomach, with metastases involving the retroperitoneal lymph nodes and causing partial obstruction and increasing obstruction to the left ureter. And if he really had lymph nodes in the neck I shall interpret them as further evidence of that diagnosis. If he had Hodgkin's disease or leukemia, I would expect to have some clue from the blood smears, but there are none recorded for me to base such a diagnosis on.

DR EDWARD B BENEDICT I do not remember this case, but from the description I do not believe it is correct to say that I saw the prepyloric area and described the region of the antrum. As I read the description given, there was an ulcer on the lesser curvature, probably in the body of the stomach.

DR ELLIS It is reported by you and the roentgenologist that no peristalsis was seen in the lower portion of the stomach.

DR BENEDICT It probably means that I did not see the antrum and pylorus.

DR ELLIS From the x ray studies and the way I read this summary I interpret them to signify involvement of the lower end of the stomach by an infiltrating type of lesion.

## CLINICAL DIAGNOSIS

Lymphoma involving the stomach wall and retroperitoneal tissues?

## DR ELLIS'S DIAGNOSES

Infiltrating malignant tumor of stomach, probably lymphosarcoma, with metastases to retroperitoneal nodes

Left hydronephrosis secondary to metastatic involvement of left ureter near left renal pelvis

## ANATOMICAL DIAGNOSES

*Mucous carcinoma of stomach, signet-ring type*

Metastases to mesenteric and retroperitoneal lymph nodes

Obstruction of left ureter from external pressure

Hydronephrosis, left

Congenital hypoplasia of kidney, right

## PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY This patient was explored by Dr Gephart and a large tumor mass found that involved half the stomach, a portion of the omentum and extended down to the region of the left kidney, which appeared to be entirely involved in the same mass. A biopsy of the tumor showed that it certainly was not lymphoma. It was an epithelial tumor with large vacuolated cells, somewhat suggestive of but by no means typical of renal-cell carcinoma, it was so reported.

The patient was transferred to another hospital, where he died a few days later. The post-mortem examination, kindly made available to us by Dr John J Larkin, the pathologist, showed a scirrhous signet-ring carcinoma of the pyloric half of the stomach. A shallow ulceration was present on the anterior wall. The tumor had grown through the gastrocolic omentum to involve the colon and had metastasized extensively in the mesenteric and retroperitoneal lymph nodes. A group of these enlarged nodes surrounded the left ureter, obstructing it by pressure and so producing a hydronephrosis. The right kidney was very small, perhaps congenitally hypoplastic, and also showed hydronephrosis. The right ureter was dilated.

## CASE 34172

## PRESENTATION OF CASE

A forty-seven-year-old woman entered the hospital complaining of pain in the left leg.

She was well until one year prior to admission, when she developed pains in the neck and back, had a gradual loss of energy, easy fatigability and an increased appetite, and had frequent loose bowel movements associated with an urgent gastrocolic reflex. There was slight exaggeration of all these

symptoms in more recent months. Six months before entry she had a barium enema, which was said to have been negative. Two weeks prior to admission the patient had several short chills and ran a slight fever. Five days prior to admission she developed discomfort in the left calf, which persisted until entry. She also had some transient pain in the right leg and during that time ran a temperature of 101°F. Upon entry she was unable to walk because of severe pain in the left calf. She gave no history of hemoptysis, nausea, vomiting or tarry stools.

Physical examination revealed a very obese woman, weighing 230 pounds. There was moderate tenderness in the left leg, extending from the ankle to 8 cm above the knee. The left calf was swollen from 1 to 2.5 cm more than the right calf. There was a positive Homans's sign in the left leg, and there were distended veins over the dorsum of the left foot. The rest of the physical examination was essentially negative.

The temperature was 99.5°F, the pulse 95, and the respirations 18. The blood pressure was 145 systolic, 90 diastolic.

Examination of the blood disclosed a hemoglobin of 13 gm and a white-cell count of 10,700, with 82 per cent neutrophils. The urine was normal. The sedimentation rate was 38 mm in one hour. The prothrombin time was 24 seconds (control, 17 seconds).

The patient was immediately started on a course of anticoagulant therapy, beginning first with heparin and then changing to dicumarol. A chest film was interpreted as negative for previous pulmonary infarcts. The fever continued, the temperature spiking to 101°F in the next few days. On the second hospital day a sharp pain developed in the left lower anterior portion of the chest, with radiation to the shoulder. A friction rub developed over this area in the chest. The prothrombin time after anticoagulant therapy was elevated to 50 seconds. The stools showed a ++++ guaiac reaction. On the seventh hospital day the patient again developed severe pain in the right calf and showed a positive Homans's sign on that side. On the ninth day a bilateral superficial femoral-vein ligation was done under local anesthesia. No thrombi were seen in the vessels. A chest film now showed linear shadows of increased density in the left costophrenic angle and possibly a small amount of fluid. The patient was placed on penicillin because of the development of a cough, with the production of a large amount of mucoid white sputum, and also the presence of rales at both lung bases. Four weeks after admission there was an exacerbation of an acute phlebitis in the left leg. The leg was painful and swollen and was about 10 cm greater in circumference than the right leg at the popliteal space. These symptoms developed under dicumarol, which

was therefore discontinued and heparin instituted. The white-cell count had risen to 23,400, with 88 per cent neutrophils. Another x-ray film of the chest showed that the left costophrenic shadow had become more linear, and there was also a small area of increased density in the posterior portion of the right lower lobe. In the fifth week pain again developed in the anterior portion of the chest, and a slight, but unmistakable, jaundice appeared. The serum albumin was found to be 2.7 gm per 100 cc, and the alkaline phosphatase was normal. The cephalin-flocculation test was +++ Munich bile was present in all the stools, many of which also showed a +++ guaiac reaction. The van den Bergh test was 2.3 to 3.3 mg per 100 cc.

An additional history revealed that one month before entry a sharp pain had developed in the right upper quadrant, associated with anorexia, heart burn and a sensation of epigastric pressure. During that period the patient had lost approximately 14 pounds. In the seventh hospital week epigastric tenderness appeared, and a questionable mass was palpable over the area of maximal tenderness in the left portion of the epigastrium. Bile continued to be present in the urine and the stools. The total protein was 4.2 gm per 100 cc, and the van den Bergh was 15.5 to 21.2 mg per 100 cc. The mass in the epigastrium was thought to have enlarged, but because of the marked obesity of the patient it could not be well outlined. Throughout the latter part of the patient's course the legs had become markedly swollen and edematous. She weighed 270 pounds terminally, and the edema had extended well up into the back. On the sixtieth hospital day the patient became restless and hyperexcitable, the respirations slowed, and she died.

#### DIFFERENTIAL DIAGNOSIS

DR. REEN A. HARWOOD: May we see the x-ray films?

DR. STANLEY M. WYMAN: This is the film taken on admission. It shows no definite evidence of intrinsic pulmonary disease. The right leaf of the diaphragm is higher than the left—higher than one would expect. The heart shadow is not unusual for a patient of this type. The second set of films, taken ten days later, shows the right leaf of the diaphragm even higher. The films were taken in the supine position, however. There is some indefinite density in the left costophrenic angle, and I believe that there is some fluid in the left pleural cavity. In the lateral film there is a suggestion that the right cavity also has a small amount of fluid in the posterior costophrenic sinus. Eight days later the film still shows indefinite linear density in the left costophrenic angle. It has become smaller, however, and there is some linear density in the right middle lung field. It seems to lie in the base of the right upper lobe anteriorly, close to the chest wall. There is a suggestion of an indefinite

round shadow posteriorly in one of the costophrenic sinuses—I believe the right. The next examination still shows density in the anterior base of the right upper lobe and the round density in the base probably of the right lower lobe. There is still fluid in the left pleural cavity and possibly in the right. The final film taken one month after this examination shows the right leaf of the diaphragm to have been elevated, considerably more so than on the previous examination. It is the only available film taken at that time. It makes one wonder about something going on beneath the diaphragm.

DR. HARWOOD: Would you say that the x-ray films are consistent with small pulmonary infarcts?

DR. WYMAN: They are consistent with multiple infarcts at the base of the right upper lobe and possibly of the left lower lobe.

DR. HARWOOD: The mention of jaundice is the first intimation that there was anything else present in this patient besides thrombophlebitis and multiple small pulmonary infarcts.

I do not get a very clear picture of what the illness was like after the appearance of jaundice. Obviously, she must have been very sick. Was that last film taken with a portable machine?

DR. WYMAN: Yes, it is a film taken at the bedside about seven weeks after the initial films.

DR. HARWOOD: The patient was probably too sick to have intensive studies such as a gastrointestinal series. There must be something in the record that would give additional information. Perhaps in summarizing the history some of the negative data were not included.

DR. MYLES P. BAKER: The alkaline phosphatase was elevated quite significantly at the first determination when she was mildly jaundiced, the figure was 14 or 17 units per 100 cc. The cephalin-flocculation test was not +++ on the first observation, it was either + or ++, and I believe that the thymol-turbidity tests were negative at first. Perhaps that is of some importance. It is true that the patient was too sick for further x-ray studies. During the period of increasing jaundice she was entirely aware of what was going on and doing her best to meet the doctors' requests, taking carbohydrates and so forth, and never presented the picture of a person in severe liver failure.

DR. HARWOOD: Was she conscious to the last day?

DR. BAKER: Yes.

DR. HARWOOD: This is one of those interesting cases in which the patient comes in for one complaint, and then, under observation, much more serious disease develops from which the patient dies. I tried, for a short while, to connect the complications with the initial complaints and wondered if she could possibly have had thrombophlebitis of the vena cava. I know very little about this condition, but I think that, if she had had a thrombosis of the vena cava that propagated beyond the entrance of the renal veins, she would not have survived such

an insult for more than a few days, so I ruled that out. Then there was the possibility of a thrombosis of the portal vein. The standard textbooks have very little to say about this, but they speak of the classic symptoms of hematemesis, ascites and severe upper abdominal pain — not a word about jaundice. I suppose that it could cause jaundice, but the information we have does not suggest portal thrombosis. For one thing, we do not know whether she had ascites. Perhaps Dr. Baker can give a little help on that. I think the weight gain of 40 pounds is rather sensational in a person who had such a serious disease, and I suspect that she had ascites as well as massive edema.

DR. BAKER: The patient had such marked edema over the back, loin and flank that it seemed as if she must have ascites, but the percussion note was resonant well over into the side of the abdomen, and one would have to say that the physical signs were not those of ascites, although it was suspected and some observers thought that it was present.

DR. HARWOOD: I am going to guess that she had ascites, but usually in portal thrombosis, the ascites develops rapidly, the taps very often are bloody, and the acute disturbance ordinarily leads quickly to death.

We have to admit that this patient had something wrong with the liver. The evidence of that is the low serum protein found in the fifth week of hospitalization, the positive cephalin-flocculation test and the rising serum bilirubin in the absence of obvious biliary obstruction. The question is, What was the matter with the liver? Did she have cirrhosis of the liver? That is one possibility, with polygonal-cell failure as a cause of the increasing jaundice and death. Dr. Baker has said that she did not present the picture of liver failure. One would expect a different type of death, perhaps a much deeper jaundice, and unconsciousness for several days before death. It seems to me that this diagnosis has been excluded.

Could the patient have had a partial obstruction of the common bile duct, as by stone, or a tumor in the region of the ampulla or in the head of the pancreas? Again, I think not, because at no time did she have clay-colored stools. She could not have developed this degree of obstructive jaundice without clay-colored stools. Obstruction of the common duct from any cause thus seems ruled out.

What are the other possibilities? I suppose that metastatic disease is fairly likely. To go back over

the record, "she developed pain in the neck and back, had a gradual loss of energy, easy fatigability and an increased appetite, and had frequent loose bowel movements associated with an urgent gastrocolic reflex," which suggest to me the possibility of some lesion of the upper gastrointestinal tract, or possibly a lesion in the pancreas.

The onset of carcinoma of the pancreas is apt to be insidious. The history does not quite fit that picture. Pancreatic carcinoma can metastasize to the liver, and I suppose it is possible for a situation to develop in which the metastases are largely in the left lobe, pressing on some of the larger bile ducts of the left lobe, whereas those of the right lobe, being uninvolved, permit the passage of bile.

One thinks of carcinoma of the stomach. Again, it does not fit the picture of the complaints that this woman had for a year before admission. The only thing that might fit is the one symptom of the presence of blood in the stool. She had it nearly every time the stool was examined. A carcinoma of the stomach or possibly somewhere else in the gastrointestinal tract might be the explanation of blood in the stools, and metastases to the liver might be the explanation of the jaundice. I have ruled out carcinoma of the large bowel because of the negative barium enema.

I should mention one final possibility, or rather, still another possibility, because there can be no "final" possibility in a case like this — that is, carcinoma of the gall bladder, the common duct or the ampulla. In all these cases jaundice is an early symptom, and it is usually complete. I think these diagnoses have been excluded because there was bile in the stools.

I have not mentioned primary carcinoma of the liver. This condition is most often found as a complication of cirrhosis of the liver. There is some evidence that this patient had cirrhosis, and it is possible that a primary tumor of the liver was also present. Such a diagnosis does not explain the blood in the stools, but this finding could be explained either by the elevated prothrombin time or by portal hypertension.

Although I am far from sure what this woman had, I am going to make diagnoses of cirrhosis of the liver, with a primary carcinoma of the liver, mostly involving the left lobe, thrombophlebitis of the veins of the lower extremities, possibly of the iliac veins, and multiple pulmonary emboli. I am

going to add a second choice — a carcinoma of the pancreas with metastases to the liver

**A PHYSICIAN** What is the possibility of liver abscess? The diaphragm was elevated. Perhaps there was some fluid there.

**DR HARWOOD** I meant to ask about the chart, but I am sure that Dr Baker would have told me if she had had a high temperature.

**DR BAKER** During the period of active phlebitis, the first week, she had a persistent fever, which subsided later.

**DR MAURICE FREMONT-SMITH** I want to say a few words about this patient, because I was in charge of her health for ten years up to the time of the last illness, including the beginning of it. Looking back, I realize that something happened that we always try to prevent. I cannot see any way now that it could have been prevented. She was a very high-strung woman, who had a tendency to diarrhea. When I first saw her, ten years ago, she had alternating periods of diarrhea and constipation. This continued off and on during the ten years that I took care of her. The diarrhea was affected by the environment. It stopped entirely after any problem that was puzzling her cleared up. Two years before admission to this hospital I did a rectal examination, and a little material being on the end of the glove, I smeared it on a slide, as I always do, and did a guaiac test, which was ++++. Two more specimens of stool were examined, and one was faintly positive and the next negative. On the basis of this blood I insisted that she have a proctoscopy and a barium enema. The proctoscopy was done by Dr Donaldson, who was able to go the full distance of the proctoscope. The mucosa was normal. No injection, ulceration or tumors were seen, except some small hemorrhoids, which were thought sufficiently bulbous and engorged to account for the bleeding. That was approximately a year before entry. Four months later the patient again had a positive guaiac test, and I wrote to her at that time "The chances, of course, are very great that there is nothing wrong except the hemorrhoids. On the other hand, we dare not make this assumption. You should have a barium enema and proctoscopy and so forth." At that time the hemoglobin was normal. Barium enema, a month later, was, as stated in the record, absolutely normal, the colon filling rapidly without constant defects or diverticula.

**DR BAKER** The picture of this woman's last illness, as far as the jaundice is concerned, was that

she was gradually developing extrahepatic obstruction, judging from the laboratory tests. She had had phlebitis in both legs, and we could not really study her adequately. There was a gradual increase in the evidence of liver-cell damage. We wondered at first about the possibility of common-duct stone, recognizing the impossibility of surgery in the presence of the illness unless faced with absolute necessity. The appearance of tenderness in the epigastrium was important. The epigastric mass became more and more obvious, and was not only tender but also the site of persistent pain. Shortly before she died it became obvious that the liver was huge.

**DR HARWOOD** In view of the information that Dr Fremont-Smith has added, may I change my diagnosis?

**DR TRACY B. MALLORY** Certainly.

**DR HARWOOD** I shall put carcinoma of the upper gastrointestinal tract — let us say of the stomach with metastases to the liver — as my first choice, and keep carcinoma of the pancreas as my second choice. Hepatoma now seems very unlikely.

**DR EDWARD HAMLIN, JR.** The only thing that Dr Harwood has not dwelt on is the rather extraordinary lack of efficacy of the treatment for phlebitis. The patient had adequate therapy by both anticoagulins and despite that developed more phlebitis. The veins were tied off at a time when neither vein showed thrombosis above the level of ligation. One would ordinarily assume that the phlebitis at least would not jump the gap. Despite adequate therapy with dicumarol, the lesion went on and both iliac veins became thrombosed. That is unusual and of some importance.

**DR HARWOOD** Suggesting a metastatic nodule pressing on the vena cava?

**DR HAMLIN** Suggesting some deficiency somewhere.

#### CLINICAL DIAGNOSES

Carcinoma of liver, metastatic, primary source undetermined, probably pancreas  
Iliofemoral phlebothrombosis  
Pulmonary infarcts

#### DR HARWOOD'S DIAGNOSES

Carcinoma of stomach  
Metastatic carcinoma of liver  
Thrombophlebitis  
Multiple pulmonary infarctions

## ANATOMICAL DIAGNOSES

*Adenocarcinoma of ascending colon, with metastases to liver*

*Thrombophlebitis of both femoral and iliac veins and of inferior vena cava*

Pulmonary emboli, multiple, with pulmonary infarction

Dependent edema

Ascites, slight

## PATHOLOGICAL DISCUSSION

DR MALLORY Post-mortem examination showed an enormous liver, weighing over 5 kg, completely replaced by metastatic carcinoma. Only very tiny patches of normal liver tissue could be found anywhere within the organ. The primary site of the tumor was in the ascending colon 3 cm above the ileocecal valve — a region where x-ray examination with a barium enema is ordinarily very accurate.

Both common iliac veins, as Dr Harwood predicted, were thrombosed, and thrombus also extended up the vena cava, practically to the mouths of the renal veins. The lower portion of the thrombus in the vena cava showed a considerable degree of organization, indicating that it had been present for a considerable time. There was massive edema of both legs and of the sacral and back regions, undoubtedly primarily dependent on thrombosis of the vena cava. The patient was perfectly vulnerable to vena-cava obstruction because she had had a previous hysterectomy, with consequent destruction of both ovarian veins, which are two of the most important sources of collateral circulation for obstruction of the inferior vena cava. She had had multiple pulmonary emboli, and these had produced

a series of infarcts in the lung, some of which were old and completely scarred, and others in all stages of more recent development down to one quite fresh one that must have occurred only a few days before death.

DR FREMONT-SMITH Was there any ascites?

DR MALLORY There was only 800 cc of fluid, which would not have been detectable in this particular patient on physical examination. Whether the extreme enlargement of the liver was sufficient to produce functional obstruction of the vena cava and thereby increase the tendency to thrombosis I cannot answer with certainty.

DR F DENNETTE ADAMS The tumor itself might account for it.

DR MALLORY There were no actual tumor nodules that could be seen pressing on or obstructing the vena cava.

DR ADAMS I meant that the presence of cancer anywhere in the body more or less tends to facilitate thrombosis.

DR FREMONT-SMITH How large was the tumor in the cecum?

DR MALLORY A small annular lesion at the time of autopsy.

DR HAMLIN To go back to the phlebitis. Despite the fact that the prothrombin time without therapy was elevated and despite the further elevation produced by anticoagulants she went on to thrombosis. I am not aware of any comment in the literature that the presence of an overwhelming malignant lesion will produce phlebitis, but it is certainly the impression of people like Dr Allen that such lesions cause phlebitis. The very fact that this rather paradoxical situation took place indicates that an overwhelming malignant tumor was present.

## BRITISH MEDICINE AT THE CROSSROADS

THE National Health Service Bill of Great Britain was enacted by Parliament on November 6, 1946, and unless changed by Parliament will become effective on July 5, 1948. It will take British medicine a long mile down the left-hand road—in company with the rest of Britain's institutions.

According to this act the Minister of Health is made responsible for setting up a service that is intended to improve the "physical and mental health of the people of England and Wales, and the prevention, diagnosis, and treatment of illness, and for that purpose to provide or secure the effective provision of services. These services will be rendered free of direct cost to the recipients.

The Ministry of Health is also charged with indirect responsibility for organizing and maintain-

ing General Medical Services, Health Centers, and all other health services, such as Maternal and Infant Welfare, Home Nursing and Midwifery. All doctors may join the new services, none are required to. Remuneration is settled by regulation and is made up of a "fixed part-salary" and a capitation fee, the latter decreasing as the number of a doctor's patients rises. The sale of practices, long an accepted transaction in Great Britain, is prohibited.

The opponents of the act point out that it means centralization of authority in the office of the Minister of Health (and England has had five Ministers of Health in seven years), intervention of a social worker between doctor and patient, the promise to its beneficiaries of complete medical, dental and nursing services without obvious cost, and the creation of a great lay bureaucracy to administer the program. It means also an estimated cost of at least \$1,800,000,000 during 1948 and, inferentially, the ultimate enslavement of all physicians, dentists and nurses into salaried government positions.

A year ago the British Medical Association, as conservative as cold roast beef was once considered to be, held a plebiscite on the act and voted 23,110 against it and 18,972 in favor, with 14,589 members abstaining. On January 31, 1948, a second plebiscite was held that resulted in a vote of 40,814 against the act, or 89.5 per cent of those voting, and 4,735 in favor of it. Another year of socialism, combined with an unfortunately dictatorial attitude on the part of Aneurin Bevan, the present minister of health, has served to crystallize the opinion of British doctors.

It is difficult to know how much of this stiffened resistance is due to an awakened appreciation on the part of the British Medical Association of what the profession stands to lose when the act goes into effect, and how much it may be the result of Mr. Bevan's apparently unco-operative and dictatorial attitude. From the debates that have taken place on the act one is forced to the conclusion that Mr. Bevan's methods have been coercive and his attitude impolitic even to the point where his judgment seems at times to be under the domination of his emotions. Win, lose or draw in this contest, it would seem that the medical profession of Great

## AN EVALUATION OF CURARE IN SPASTICITY DUE TO SPINAL-CORD INJURIES\*

ROBERT A. KUHN, M.D.,† AND DONALD S. BICKERS, M.D.‡

FRAMINGHAM, MASSACHUSETTS

IN 1850 Claude Bernard<sup>1</sup> demonstrated the site of action of curare to be the neuromuscular junction. His experiments have been verified by numerous investigators, and in 1935 West and King<sup>2</sup> clarified the mode of action and enumerated the pharmacologic properties of the drug. It was not until 1943 that Wintersteiner and Dutcher<sup>3</sup> crystallized the quaternary ammonium salt, d-tubocurarine chloride. Recent availability of this pure preparation has stimulated clinical and pharmacologic investigations.

The gross effects of curare on the normal human subject have been thoroughly investigated. The intrinsic musculature of the toes and eyes demonstrates early paresis, which successively involves the muscles of the limbs, head and neck. Inter-costal muscle relaxation is soon followed by paralysis of the diaphragm. During the early stages of curarization, the patient complains of blurring and fuzziness of vision. The eyelids droop, diplopia develops, and the jaws relax. There is weakness and heaviness of the neck muscles progressing to head drop. Further administration of the drug produces complete peripheral paralysis and, finally, respiratory arrest.<sup>4</sup> These signs and symptoms disappear in reverse order, and the rate of disappearance is dependent upon the nature of the curare preparation administered.

Although it is known that curare exerts its influence primarily at the myoneural junction, the exact mode of action remains in doubt. Eccles, Katz, and Kuffler<sup>5-10</sup> demonstrated that the end-plate potential in fully curarized muscle rises to sub-threshold levels and subsides without initiating muscle response. The size of the potential—that is, the degree of depolarization—depends in part on the concentration of the curare in the muscle. The degree of block is controllable, and certain frequencies can be suppressed. This action may well explain obliteration of various involuntary move-

ments while normal voluntary contractions continue.<sup>11</sup>

Clinically, curare has been used with value in a number of conditions necessitating muscle relaxation. Curare therapy of tetanus has met with some success,<sup>12-15</sup> and convulsions incident to shock therapy are effectively diminished.<sup>16-18</sup> However, it is in anesthesiology that this drug has achieved its maximal usefulness to date. In 1942, Griffith<sup>19</sup> reported the use of curare as an adjuvant to general anesthesia, and numerous excellent studies in succeeding years have thoroughly established its value in this field.<sup>20-23</sup>

In 1942 Denhoff and Bradley<sup>24</sup> conducted a controlled study of the effectiveness of aqueous curare in relieving the spasms of children with cerebral palsy. They concluded that progress under physical therapy was definitely accelerated in these subjects. Muscular relaxation with maximal therapeutic dosages was maintained for a period of approximately four days. Burman,<sup>25</sup> Bennett<sup>26</sup> and Schlesinger<sup>27</sup> reported similar success in patients exhibiting spasticity and rigidity.

Recent reports have indicated that curare might offer valuable aid in the amelioration of spastic paraplegia and paraparesis.<sup>21, 28, 29</sup> Schlesinger<sup>27</sup> administered aqueous curare to 11 patients with extreme spasticity due to spinal-cord injuries and obtained excellent but transient relaxation. A suspension of d-tubocurarine chloride in a peanut-oil and white-wax mixture was prepared in an effort to retard the rate of absorption. The curare effect was found to be prolonged up to three days in some cases, and effective reduction of spasticity was not accompanied in any case by unpleasant side reactions. The effect of the curare in oil on patients exhibiting voluntary function masked by spasm seemed more dramatic than that observed in paraplegic patients.

Severe spasm of muscle groups innervated below the level of the cord lesion is frequently a major manifestation of spinal-cord injury, whether due

‡Assistant resident in neurology, Montefiore Hospital, New York City; formerly research fellow in neuropathology, Neurological Unit, Boston City Hospital.

Here, and elsewhere in this article, the term "spasticity" refers to the involuntary muscular contractions occurring in strict *à muscle groups* innervated below the level of the cord lesion. More detailed descriptions of these myoclonic events are given in the case reports presented below.

extension in the lumbar spine for normal hip motion while splinted by his spastic muscles. This is not efficient ambulation and is never recommended as the procedure of choice, but only as a last resort under these circumstances.

The height of the back brace has been the subject of much discussion and experiment, but the optimum level has proved to be 4 cm below the inferior angle of the scapulas. This is sufficiently high to allow good articulation with the lower portion of the thoracic cage and yet low enough to permit free action of the scapulas and other elements of the pectoral girdle. Higher back braces are superfluous since the thoracic cage is well supported structurally by ligaments and the pectoral girdle. A positive objection to braces extending above this point is the

ward. Unless a caliper lock is employed in addition to stabilize this ankle joint, some stability may be sacrificed. This is justifiable since it means the difference between a brace that is practicable for use and one that is not.

### Miscellaneous (Fig 7)

In patients whose injuries occur above the first thoracic segment, certain special appliances may be made for the arms, depending upon the degree of brachial-plexus involvement. Among these are the triceps brace to maintain the arms in extension and a leather wristlet to maintain wrist stability. The knee strap is used when necessary to prevent genu varus or valgus, and the "T" strap performs a similar function at the ankle joint. The cock-up splint is made of a wire frame with transverse canvas web supports.<sup>7</sup> The sleeper brace and cock-up splints are used in the earlier stages (I and II) before the patient becomes ambulatory as an aid in preventing flexion contractures of the ankle and knee. The detachable spreader bar is occasionally employed in teaching the swing through in Stage IV, but further use is discouraged; it is attached to the medial uprights at ankle level by means of bolts with wing nuts. The Taylor back brace, not shown, is used for correction in the occasional case in which severe kyphosis develops in high thoracic and cervical injuries.

### DISCUSSION

It will be noted in the foregoing discussion of the four general types of supports that the indications are based primarily on the assumption of a complete lesion at the level indicated. Although such an injury is actually present in the majority of patients, a smaller proportion of incomplete injuries of the cord and cauda equina will be encountered. In such cases it is impossible to state categorically in advance exactly what type of appliance will be indicated, not only because of wide variance in the initial pattern of muscular dysfunction but also because there may be gradual improvement in muscular power over a period of months after the initial trauma. Muscle analysis is indispensable in partial lesions as the initial step when the patient is ready for bracing. With this information at hand and the specific function performed by each type of appliance borne in mind, a rational approach may be made to the specific problem presented. In cervical-cord injuries the extent of the brachial-plexus involvement will determine the appliances necessary for the upper extremities.

Although a detailed study of ambulation is beyond the scope of this communication, it is essential in any discussion of braces at least to mention the type of gait that may reasonably be employed with a given appliance. Patients requiring only drop-foot braces approach most nearly the normal gait. They may use ultimately either one or two canes and walk

FIGURE 7 Miscellaneous Braces

interference offered to the proper use of crutches, which become entangled with the back-brace extension. The height has a direct bearing on the total weight, which at best exceeds that of any other type. Attempts to substitute duraluminum for the uprights and transverse struts of the back brace have resulted in failure because of the great stress that the appliance is called on to bear. Some weight may be spared with substitution of sheet duraluminum for the 17-gauge steel in the main body of the back support, but further use of this material is foredoomed to failure.

It was primarily for patients with back braces that the caliper with a detachable drop-foot spring was developed, since the stirrup-type leg brace with shoes and back brace attached requires the assistance of one or two persons in application and removal of the unwieldy device. With calipers and a detachable drop-foot spring the patient can wear shoes continually, insert the calipers into the shoes and then proceed to lace the brace from below up-

almost normally except that they tend to proceed on a rather wide base with steppage gait. Initially, it may be necessary to train such patients with crutches instead of canes, but the use of crutches should be discouraged as rapidly as possible — the obvious objections to crutches are that they call attention to the patient's handicap and promote a feeling of dependency. The type of gait to be employed by patients with long leg braces will depend on the degree of function remaining in the thigh flexors. Should the thigh flexors be adequate to advance the legs even though not strong enough to support the patient's body weight, either the four-point or the more rapid two-point crutch gait is feasible. In either case, he should also be taught the swing through, which is the most rapid of all gaits and may be required in situations in which speed is desirable, as in crossing streets with traffic lights. This type of gait can be taught to any properly prepared patient with a complete or partial lesion below the first thoracic segment and is mandatory for those with loss of thigh flexors and higher lesions (the second lumbar segment upward). The pelvic-band group will not usually exhibit enough function to allow the two-point and four-point gaits and consequently must be taught the swing through with the preliminary temporary swing-to gait. For patients requiring back braces the only practicable gait for distance walking is the swing through, which is taught to all patients except those with lesions above the second thoracic segment that are so severe as to cause gross impairment of arm function. As in the pelvic band group, the swing to is taught as a preliminary to learning the swing through. The swing to is retained only for maneuvering in close quarters where the lack of space renders the swing through impossible. Since the hip joint must be movable for efficient ambulation, it is incumbent on these patients to exercise more skill and balance than lower injuries demand. The patient should not be permitted to attempt a swing to until he has thoroughly mastered the art of balancing with first one and then the other crutch off the floor, unsupported by either an instructor or other artificial means. The poise and sense of confidence gained thereby is basic in the subsequent steps of ambulation progressing through the swing to to an efficient swing through. Lesions high enough to involve the brachial plexus usually force the patient to walk with a swing to or shuffle. This has proved practicable with one of our patients with a complete motor lesion below the fifth cervical segment except for some intact fibers in the seventh and eighth cervical segments. Concurrently and later, all patients must go through a period of intensive mat work and other calisthenics designed to strengthen the pectoral girdle and arms to a point that will permit the stress of weight bearing demanded for ambulation. This is particularly important in the group with higher injuries.

The knee lock used in construction of the long leg braces is recommended after testing of several more complicated types. It is of simple, rugged construction requiring a minimum of machining and repair. The gravity lock is easily placed and fool-proof during use. More elaborate locks are more expensive and prone to damage by twisting or bending.

The width of calf and thigh bands is of practical importance. As a general rule, best results are obtained from narrow bands. Although no difficulties have been encountered, owing to the youth of the patients, circulatory embarrassment may well result in older patients if calf and thigh bands are too wide. This precaution should apply to any patient with venous varicosities, arteriosclerotic changes or other impairment of peripheral circulation.

Steel is the material of choice though its weight is somewhat greater than that of duraluminum. Its durability and capacity to withstand torsion and stress, particularly of the higher braces and in heavy patients, make it irreplaceable by any of the light alloys available. Observations on duraluminum braces constructed here and at other institutions indicate that joints deteriorate rapidly and that twisting necessitates frequent attempts at adjustment, which are rarely, if ever, successful. The calf and thigh bands used on these braces are not of the contour-fitting type advocated by Hessing,<sup>1</sup> since no weight-bearing function is required of them. The considerable time and expense associated with the building of such bands may be avoided.

### SUMMARY

Preliminary rehabilitation procedures prior to the fitting of braces on patients with spinal-cord injuries are outlined.

Factors involved in choosing the proper brace for patients with spinal-cord injuries, with special reference to the level of injury, are discussed.

Four main types of brace are presented in detail, with the indications for each.

The type of gait to be expected for each level is described.

I am indebted to Mr. Walter Gavin of the Orthopedic Shop, Cushing Veterans Administration Hospital, for his co-operation and assistance.

# ULCEROGLANDULAR TULAREMIA TREATED WITH STREPTOMYCIN

## A Report of Two Cases

CAPTAIN RAYMOND E LESSER, M C, A U S., AND MAJOR SIDNEY MILLER, M C, A U S

HEILMAN'S<sup>1</sup> demonstration of the effectiveness of streptomycin against *Pasteurella tularensis* in vitro and in vivo has found application in the treatment of tularemia in man. The cases presented below are considered to be of interest because they report additional experience with the use of streptomycin in the treatment of tularemia. Furthermore, they afford an interesting comparison of the effectiveness of treatment of the acute and chronic phases of the disease.

### CASE REPORTS

**CASE 1** A 39-year-old man was hospitalized on February 14, 1947, complaining of "cold sensations," pain in the eyes and back and coughing and sneezing of 2 days' duration.

The past history as obtained at the time of admission was of no related significance except for typhoid fever 29 years previously and malaria in 1930.

Physical examination revealed a haggard but well nourished man who appeared moderately ill. The skin was livid

scratched his right middle finger with a briar, but he had not skinned the rabbits. On the following day a localized area of infection was noted at the site. On the day of admission he experienced chills, fever, headache, general malaise and a tender swelling in the right axilla. He also volunteered the information that "rabbit fever, typhus fever and hemorrhagic fever" were endemic in his home town, Americus, Georgia, the locale of his rabbit hunting. Agglutinations and a culture and smear of the ulcerated area were made, and streptomycin — in a dosage of 3 gm daily — was given. Treatment was continued for 7 days. Within 24 hours the patient experienced dramatic subjective improvement, and in 48 hours the temperature began to regress and the lesion to undergo involution. At the end of 7 days the temperature became normal and remained so for the duration of the hospital stay of 54 days. The local lesion and axillary adenopathy completely subsided 4 weeks after the institution of streptomycin.

The subsequent clinical course was uneventful. The pertinent laboratory data are summarized below, and the clinical course is graphically represented in Figure 1.

On February 14 examination of the blood disclosed a white-cell count of 12,000, with 70 per cent neutrophils, 23 per cent lymphocytes and 7 per cent monocytes. The urine was normal. The blood Kahn test was negative. On February 25 a blood culture was negative, and smear and culture of the ulcer were negative for *Past. tularensis*, agglutinations for the organisms of typhoid, paratyphoid and undulant fever, as well as those for salmonella and typhus (proteus x 19), were negative. Agglutinations for *Past. tularensis* were + + + + in a dilution of 1:40, + + + in one of 1:80 and negative in one of 1:160. On March 6 the agglutination was + + + + in a dilution of 1:1280, + + in one of 1:2560 and negative in one of 1:5120. On March 10 the agglutination was + + + + in a dilution of 1:160 and + + in one of 1:1280. On March 19 the agglutination was + + + + in a dilution of 1:320, + + in one of 1:640 and negative in one of 1:1280, and on April 7 it was + + + + in a dilution of 1:160, + + in one of 1:640 and negative in one of 1:1280.

Three x-ray examinations of the chest during the initial 10-day period were negative.

**CASE 2** A 26-year-old paratrooper was hospitalized on April 24, 1946. He complained of right axillary and right epitrochlear swelling associated with numbness of the fourth and fifth fingers of the right hand of 2 months' duration. During that time he had lost 17 pounds in weight and had observed that the "swellings" had been increasing in size, at the time of admission they had become painful. The patient had been rabbit hunting in January, previous to and at the time of which he had had a "sore" on the ring finger of the right hand. After he dressed the rabbits the "sore" on the right ring finger became deeply infected, and red streaks extended to the wrist. Two weeks later he experienced chills and fever. After these symptoms had persisted for 1 week, he reported to another Army installation, where he was treated for malaria, the fever persisting for 1 week after hospitalization. On the day of admission he had noted the onset of aching in the muscles and joints.

Physical examination revealed a well developed man, who showed signs of recent weight loss. There were numerous small, nontender shotty lymph nodes in the anterior cervical triangle. In the right axilla there were three tender nodes, which were rubbery in consistency and measured 1 or 2 cm in diameter. A similar tender right epitrochlear node was present. When palpated, a linear structure that was considered to be the ulnar nerve moved on manipulation of the node and produced a shocking type of ulnar paresthesia. An ulnar hypesthesia of the fourth and fifth fingers was also present. A circular scar, measuring 5 mm in diameter, was on the medial dorsal surface of the terminal phalanx of the fourth finger of the right hand.

FIGURE 1 Pertinent Laboratory Data and Clinical Course in Case 1

Except for a moderately injected throat and increased breath sounds at the left base, the findings were not remarkable.

On the following day the patient began to manifest a spiking, remittent type of fever. The examining ward officer believed that the patient had a virus pneumonia. When the temperature continued and coarse rales were noted at the left base, previous supportive and symptomatic measures were supplemented by 300,000 units of calcium penicillin in beeswax and peanut oil each day. Despite this therapy the clinical course remained unchanged. Two weeks after admission the examining ward officer first noted an umbilicated, ulcerative lesion with a necrotic center on the dorsal surface of the right middle finger at the distal phalangeal joint, measuring 1.5 cm in diameter. The edges were raised, erythematous and indurated. A single tender, firm lymph node measuring approximately 3 cm in its greatest diameter was palpable in the right axilla. The presumptive diagnosis of tularemia was entertained, and corroborative studies were made.

Further questioning revealed that the patient had been rabbit hunting 3 days before admission. He stated he had

Examination of the blood disclosed a white-cell count of 7500, with 55 per cent neutrophils. A smear was negative for malaria. The urine and the serologic findings were normal. The corrected sedimentation rate was 11 mm in 1 hour (Winthrope method). Two agglutinations for *Past tularensis* were negative. The presumptive diagnosis of tularemia was so strongly held that it was requested that the specimen be sent to the Service Command Laboratory, where agglutinations for *Past tularensis* were reported + + + + in a dilution of 1:320 and + + in one of 1:2560. A ray examination of the chest was negative.

During the hospital stay the patient was afebrile. With the establishment of the diagnosis of tularemia streptomycin therapy consisting of 0.2 gm. every 4 hours for a total of 4.4 gm. over a 4-day period was instituted. During treatment

There was generalized lymph node enlargement, a 1-cm., nontender right axillary node several pea sized tender left axillary nodes, two pea sized nontender right epitrochlear nodes three similar nontender left epitrochlear nodes and bilateral tender inguinal nodes on the left.

The temperature was 97.6°F. the pulse 80 and the blood pressure 110/85.

The patient remained afebrile throughout the hospital stay. Shortly after admission, the left epitrochlear and left inguinal lymph nodes were surgically removed. The former was extracted and cultured on cystine blood agar. However no growth was obtained. The inguinal node was sent to the area pathology laboratory, which reported chronic lymphadenitis. A ray examination of the left hip was negative.

Because of the rise in agglutination titer, as well as the significant change in clinical course it was believed that the

\*Streptomycin, in total dosage of 4.4 gm. given between May 11 and 15

†Streptomycin, in total dosage of 12.0 gm., given between March 4 and 11

there was beginning regression of the lymphadenopathy and diminution in the weakness. One week later all tenderness of the lymph nodes had subsided but slight residual adenopathy remained. The patient, who was much improved subjectively, was discharged to duty 35 days after admission.

After discharge he was seen periodically as an outpatient. Objective and subjective improvement continued with complete resolution of the adenopathy and with ability to carry on with military performance. However, he still complained of some weakness and did not completely regain the weight that he had lost.

Determinations of agglutination for *Past tularensis* were made monthly and remained constantly + + + + in a dilution of 1:160 during the ensuing months.

Except for weakness and nausea following exertion the patient remained well until December. He experienced a mild aching sensation in the left thigh, left leg and left lower quadrant. When he arose each morning associated malaise returned. The symptoms were of gradual onset but increasing severity. On January 6 1947 he noted for the first time a recurrence of lymphadenopathy in the left epitrochlear region. At the next dispensary an agglutination for *Past tularensis* was reported as + + + + in a dilution of 1:1280—a higher titer than at any time previously or subsequently in the illness. On February 3 the aching pain in the left axilla and left leg became severe. The leg pain apparently originated in the left inguinal region and was associated with left inguinal adenopathy, the pains radiated down the leg were aggravated by exercise and were relatively constant. A novocain injection into the left groin produced relief for 1 hour. Neuropsychiatric examination revealed no psychoneurotic tendencies.

On February 24 the patient was readmitted to the hospital because of the symptoms and clinical course described above. Physical examination revealed a slightly toxic and chronically but not seriously ill patient.

patient was experiencing a relapse. Therefore on March 4 streptomycin was started, consisting of 3 gm. daily for 7 days in divided doses for a total of 21 gm. At the conclusion of therapy the patient felt markedly improved, and the adenopathy slowly regressed. Previously, he had lost 15 pounds in weight. One month after the conclusion of therapy he had regained 7 pounds. There was no adenopathy and the agglutination determination was + + + + in a dilution of 1:160 and + + in one of 1:320. However the last determinations were + + + + and + + in dilutions of 1:160 and 1:640 respectively, on May 25. Urinalyses were negative during the period of observation. An electrocardiogram was normal. A bromsulphalein test (5 mg. dose) showed no retention of the dye in 1 hour. The corrected sedimentation rate was 9 mm in 1 hour (Winthrope method) on two occasions.

The agglutination determinations are presented in Table 1

## DISCUSSION

The effectiveness of streptomycin treatment in the cases reported above parallels that which has appeared in the literature to date.<sup>1-12</sup>

Case 1 afforded no particular problem once the diagnosis had been established. The response was excellent, so far as both morbidity and mortality were concerned, and the effectiveness of streptomycin was again demonstrated. Case 2, however, presented a more complex problem.

Several features present themselves for discussion. The effectiveness of streptomycin when latency exists between initial onset of the disease and the institution of treatment does not seem to be en-

hanced Although the clinical response to streptomycin was definite, the subsequent course of the disease indicates probable inadequacy of dosage initially It may also indicate decreased effectiveness of treatment when a delay occurs between the initial phase of the disease and the institution of therapy The recurrence of symptoms associated with variation in serologic titer of significant degree suggests that criteria for chronicity should be extended farther than the number of days of temperature above 98.6°F, the duration of buboes and the number of days in bed, as suggested by Foshay and Pasternak.<sup>6</sup> Evidence for relapse as manifested by serologic and clinical changes may be correlated with the retention of living bacteria within the recovered patient The inability of streptomycin to effect lasting remission in Case 2 was probably due not only to this fact but also to development of resistance by the organism to the antibiotic agent The initial amount of streptomycin used may be considered inadequate in the light of current knowledge of organism sensitivity It is unfortunate that such studies were not available in this case, in which the course of events suggests the importance of early control of the disease before maximum invasion has occurred

## SUMMARY

Two cases of ulceroglandular tularemia treated with streptomycin are presented in which the course paralleled that which has appeared in the literature to date

The mechanics for failure to effect a lasting cure in one case are discussed

## THE EFFECT OF SURGICAL OPERATIONS ON THE BROMSULFALEIN-RETENTION TEST\*

HENRY J. TAGNON, M.D.,† GUY F. ROBBINS, M.D.,‡ AND MARY P. NICHOLS, A.B.

NEW YORK CITY

THERE are several reports in the literature dealing with the effect of surgical operations on liver function. The available material was recently reviewed.<sup>1,2</sup> Most workers report changes in a high proportion of patients after surgery under general or spinal anesthesia. The hippuric acid test was used in several cases but has been criticized on theoretical grounds. The principal objection is that it depends on the integrity of kidney function, which may be impaired immediately after a surgical operation. Other authors have reported results obtained with the bromsulfalein-retention test using an injection of 2 mg. of the dye per kilogram of body weight.<sup>2</sup> It has recently been shown that the bromsulfalein-retention test is rendered more sensitive by the use of a dose of 5 mg. per kilogram of body weight.<sup>3</sup> Finally, in view of the report that mechanical trauma to the liver may produce impairment of its function,<sup>4</sup> it seemed worth while to evaluate the effect on the liver of extra-abdominal operation so as to exclude the possible factor of mechanical trauma.

The work reported below represents an attempt to detect changes in the function of the liver following extra-abdominal operations by means of the bromsulfalein-retention test modified so as to make it more sensitive.

In addition to this procedure blood was obtained for thymol-turbidity and cephalin-flocculation tests.

Bromsulfalein retention was determined on non-fasting patients according to the method of Mateer et al.,<sup>3</sup> 5 mg. per kilogram of body weight and a thirty-minute period being used. Readings of bromsulfalein retention were made by comparator block matching.

The cephalin-flocculation test was done by the method of Hanger,<sup>5</sup> using the Difco reagent. A single twenty-four-hour reading of the reaction was recorded.

In the thymol-turbidity test the technic described by MacLagan<sup>6</sup> was used and the values expressed in cubic centimeters of a suspension of barium sulfate as recommended by Ley et al.<sup>7</sup> The reaction of the thymol reagent as measured by the Beckman electrometer was pH 7.8.

\*From the Sloan-Kettering Institute for Cancer Research and the Memorial Hospital for the Treatment of Cancer and Allied Diseases.

†Senior fellow, National Research Council.

‡National Cancer Institute surgical fellow.

\$Kindly supplied by Hynson, Westcott and Dunning, Philadelphia. With 5 mg. of dye per kilogram of body weight, a correction factor is used in the readings.

## MATERIAL AND METHOD

A group of 20 patients admitted to the Memorial Hospital for operative treatment was studied. Half the patients (Group I) were on the Head and Neck Service, and the other half (Group II) on the Breast Service. This type of patient was selected to avoid the inclusion of cases in which intra-abdominal procedures had been performed. The possibility of mechanical trauma to the liver was therefore excluded. In each group of 10, the patients were unselected and were studied as they were admitted on the wards.

The state of nutrition of each patient was appraised by means of the history and general appearance, the weight and the detection of clinical signs of nutritional deficiencies. All patients studied were found to be in a satisfactory state of nutrition except 1 (Case 7), who was obese. Clinical evaluation of pre-existing liver damage was done by questioning about the existence of past liver disease, exposure to toxic factors including alcoholism and the detection by physical examination of such signs as enlargement of the liver and spleen, icterus, collateral circulation and spider angiomas. By these criteria, all patients were found to be free of clinically detectable liver disease before and after the operation period except 1 (Case 2), whose liver was slightly enlarged and who had a past history of heavy alcoholic intake.

Two patients, Cases 12 and 14, were found to have high blood pressure on admission. The former had a blood pressure of 170 systolic, 120 diastolic, auricular fibrillation and slight dyspnea on exertion, but no peripheral edema. Functionally she belonged to Group II-C of the classification of the New York Heart Association, her cardiac status was not clinically altered by the operative procedure. The other patient had a blood pressure of 210 systolic, 90 diastolic. Her only cardiac symptom was slight dyspnea on exertion. This case should be considered in Group I-B of the classification of the New York Heart Association; the operation did not alter her cardiac status.

The over-all clinical picture, including the type of operation and its duration, is presented in Table 1. Some patients (Cases 1 to 10) received intravenous pentothal sodium as a general anesthetic, in others (Cases 11 to 20) operation was performed under general anesthesia by nitrous oxide, oxygen and ether. Every patient prior to operation received an injection of 15 mg. of morphine, 0.6 mg. of atropin and 100 mg. of nembutal or 100 mg. of luminal.

In each group the patients were classified according to decreasing severity of operation. Thus in Group I, the most serious operation was performed in Case 1, and the least serious in Case 10. In Group II the most serious operation was performed in Case 11, and the least serious in Case 20. Evaluation of the gravity of the surgical procedure is

admittedly arbitrary and was based mainly on two criteria: extent of trauma, with particular emphasis on bone resection, and duration of the procedure. This classification does not pretend to be an absolute one but rather reflects the general trend of severity within each group.

The blood pressure was followed by readings obtained at fifteen-minute intervals during the entire procedure and immediately thereafter. A fall of blood pressure of 20 to 40 for not longer than half an hour was considered a sign of mild shock. A more serious manifestation of shock was not observed. Replacement fluids given in the course of the operation are indicated in Table 1. Fever was absent at the time of operation in all patients.

On admission the bromsulfalein-retention test was carried out, and blood was obtained for the thymol-turbidity and cephalin-flocculation tests. This procedure was repeated within an hour of the patient's return from the operating room. In most cases the patient was still under the influence of the anesthetic when the second test was done. At least a one-day interval separated the preoperative and postoperative tests. The patient was tested again once or twice several days later when he was well on the way to recovery.

## RESULTS

### *Bromsulfalein Clearance*

Before the operation the retention of bromsulfalein in all patients did not exceed 10 per cent, with the exception of 1 patient (Case 7), who had a retention of 12 per cent. The upper limit of normal retention of bromsulfalein after thirty minutes with the technic used is 10 per cent, and all patients studied can therefore be considered as having had a normal test preoperatively.

Immediately after the operation, there was a marked elevation of the amount of bromsulfalein retained in the blood in several patients; the increased retention could be considered significant in Cases 1 to 9, 11, 12, 14, 15 and 16. The elevation was absent or insignificant in the others. The increased retention was pronounced in 6 cases in Group I (Cases 1, 2, 3, 5, 7 and 8), the greatest retention being observed in Case 8, and in 2 patients in Group II (Cases 11 and 12). The increased retention was not maintained, and the test returned toward normal in the following days.

### *Thymol Turbidity*

The usually accepted upper limit of normal with this test is a turbidity corresponding to 1.75 cc. of barium sulfate suspension. Four of the 20 patients initially had a somewhat elevated test (Cases 1, 11, 14 and 20). There was no general increase after the operation. One patient (Case 7) showed a

significant increase. In the others the thymol turbidity either remained unchanged or decreased.

### *Cephalin Flocculation*

A normal test is represented by absence of flocculation (0) or a + reaction. Five patients (Cases 1, 4, 5, 8 and 10) had an abnormal flocculation test preoperatively. The change in cephalin flocculation postoperatively was not consistent, increasing in some patients and decreasing in others. Most patients in Group II, with the exception of Case 19,

In Group I there was no absolute correlation between the severity of the operation and the amount of dye retained postoperatively. For instance, the patient (Case 8) whose operation was considered less severe than that on the 7 patients preceding her in the classification of Table 1 had the highest degree of retention. In Group II the correlation was better, since the greatest retention of dye was observed in the first patients of the group (Cases 11 and 12). If the two groups of patients are considered together, there seemed to

had a normal cephalin flocculation initially, which remained normal postoperatively.

### DISCUSSION

The data show that in 14 of the 20 patients there was a significant increase in the retention of bromsulfalein postoperatively as compared to the amount retained before the operation. The retention of dye was very pronounced in several cases. Whereas all patients, with the possible exception of 1 (Case 7), initially had a normal clearance, the increased retention following the operation in 14 cases resulted in postoperative values that were considered abnormal and indicative of liver dysfunction.

be a correlation between severity of operation and retention of dye, since the last patients of Group II, who probably underwent the least severe type of surgical procedure, also showed the smallest degree of retention postoperatively.

It is obvious that the criteria by which the severity of the operations was evaluated are not absolute, and other factors than the ones considered above may have played a role.

The mechanism by which a surgical operation produces such marked changes in bromsulfalein retention is not entirely clear. Liver dysfunction is a conspicuous and early sign of shock.<sup>8</sup> The early stages of shock may not be manifested by a fall of blood pressure at a time when anoxemia of internal

organs such as the liver and the kidney has already taken place.<sup>8</sup> It is therefore conceivable that although the patients in this series either did not experience a fall in blood pressure or at most showed a slight and transitory fall, they had a certain degree of anoxemia of the liver during the operation, explaining the reduced ability of this organ to clear the blood of dye. In that case, the increased retention of bromsulfalein following an operation might be significant as a measure of the amount of injury inflicted on internal organs by a surgical procedure.

If the changes in bromsulfalein retention observed denoted liver dysfunction, the abnormality appeared to be reversible and did not persist longer than a few days. Normal or nearly normal values were observed in almost all patients a few days after the operation.

So far as the thymol turbidity and cephalin flocculation were concerned, it was not expected that the tests would show any significant change. These procedures depend entirely on the presence of an abnormal globulin constituent in blood plasma, and

applied to a distant anatomic region. A direct mechanical trauma to the liver during the operation, as in the course of an intra-abdominal operation, seems to be ruled out in the patients of this series by the type of subjects selected.

The anesthesia may have been a contributory factor, although pentothal and ether are not considered to be liver poisons. Nevertheless, this factor cannot be entirely ruled out. The extent of the surgical procedure and its duration, regardless of the type of anesthesia, appeared to be more important. The data do not indicate that the age of the patients was a decisive factor in the production of postoperative liver dysfunction as shown by the retention of bromsulfalein in the blood.

this could hardly be expected to occur during the relatively short duration of the operation. The absence of definite changes in the two tests during the postoperative period indicates that the liver dysfunction detected by the bromsulfalein test in the series of patients studied was not pronounced, and confirms its transitory nature.

These results largely confirm those obtained by previous workers and indicate definite impairment of liver function after protracted surgical operations, even when the operative site is such that mechanical trauma to the liver is ruled out.

The changes in liver function are probably significant in that they may represent one of the factors contributing to a complex syndrome called "post-

operative disease." The prevention and control of these changes deserve further study

### SUMMARY

There was a significant increase in the retention of bromsulfalein immediately after an extra-abdominal operation in 14 of 20 patients studied. No similar changes were observed in the thymol-turbidity and cephalin-flocculation tests.

There was a certain degree of correlation between the severity of the operation and the postoperative appearance of an impaired ability of the liver to clear the blood of bromsulfalein. Other factors, such as anesthesia by ether or pentothal sodium and the age of the patients, appeared less important. The significance of these facts in relation to the physiologic changes brought about by a surgical operation is discussed.

We are indebted to Dr. Hayes Martin and Dr. Frank E. Adair for permission to study their patients.

## THE PROBLEM OF SULFONAMIDE-RESISTANT HEMOLYTIC STREPTOCOCCI\*

THOMAS L. HARTMAN, M.D.,† AND LOUIS WEINSTEIN, M.D.‡

### BOSTON

PREVIOUS reports have discussed the problem and circumstances of the development of sulfadiazine-resistant hemolytic streptococci in the armed forces of the United States during 1944.<sup>1-8</sup> In a civilian community the occurrence of infections due to sulfonamide-resistant hemolytic streptococci<sup>9</sup> indicates that these organisms have had a wide distribution throughout the general population via military personnel. The possibility that these resistant organisms might become an epidemiologic and therapeutic problem in civilian life cannot be dismissed on the basis of the available information. Also, the likelihood of such a situation arising in the general population — that is, the development of sulfonamide-resistant or penicillin-resistant strains of hemolytic streptococci under the common therapeutic and prophylactic regimens — should be considered, and efforts directed toward its prevention.

A study of the sulfonamide sensitivity of hemolytic streptococci in the general population would indicate the prevalence of known sulfonamide-resistant strains and also whether there are naturally resistant strains that might assume increased resistance under proper circumstances. It is the purpose of this paper to present the results of sulfonamide-

sensitivity determinations of hemolytic streptococci as they occurred in a New England population, as well as an analysis of the available information pertaining to the conditions under which sulfonamide-resistant hemolytic streptococci developed.

### METHODS

The cultures studied were obtained from patients admitted to the Evans Memorial and Haynes Memorial Hospitals, serving Boston and the suburban areas surrounding it, during the fall and winter of 1946-1947. These patients were admitted to the hospital because they had clinical evidence of a streptococcal infection or were admitted for observation or study and found to harbor hemolytic streptococci. Most of the strains of hemolytic streptococci were isolated from the nasopharynx of patients who had clinical scarlet fever, others were obtained from streptococcal carriers or patients with pharyngitis, otitis media, pneumonia or wound infections due to the hemolytic streptococcus.

Cultures were obtained by swabbing of the nasopharynx or infected areas with culture swabs. The swabs were wiped on 2 per cent blood-agar plates, streaked and incubated aerobically at 37°C for twenty-four hours. Single colonies of beta-hemolytic streptococci were picked and transferred to blood-agar plates or to broth for further identification and study. The hemolytic streptococci isolated were grouped and typed by the precipitin technique, antiserums for Types 1 to 47 were available. The

sulfonamide sensitivity was determined by the method of Wilson,<sup>11</sup> horse serum being used, susceptible and resistant strains were always run as controls. Only organisms growing in a concentration of 5 mg per 100 cc of sodium sulfadiazine were considered to be resistant. Occasionally scant growth appeared in the tube containing a concentration of 1 mg per 100 cc, however, owing to the conditions of this test, growth in this tube was not considered evidence of resistance.<sup>11, 12</sup>

### RESULTS

One hundred and sixty-seven Group A hemolytic streptococcus strains isolated during the fall and winter of 1946-1947 were tested for sensitivity to the action of sulfadiazine. The type distribution and sulfonamide sensitivity are indicated in Table 1. Types 18, 30 and 31 were the most prevalent, however, there was no predominant epidemic-type strain prevalent in this area. Types 1, 17 and 19, which were the predominant types in the Navy,<sup>1, 2</sup> did not assume any epidemic prominence in this study.

Of 167 strains of Group A hemolytic streptococci tested for sensitivity to the action of sulfadiazine, 166 were sensitive to its action—that is, none grew in a concentration of sodium sulfadiazine as great as 5 mg per 100 cc. One strain, a Group A, Type 19 hemolytic streptococcus, was resistant to the action of sodium sulfadiazine in a concentration of 25 mg per 100 cc. This sulfonamide-resistant strain was isolated from a patient who had clinical scarlet fever and later developed electrocardiographic and clinical evidence of rheumatic heart disease. This strain was sensitive to 0.0078 units of penicillin, as determined by the method of Rammelkamp.<sup>13</sup>

### DISCUSSION

Recent publications have offered some suggestions regarding the possible origin of sulfonamide-resistant streptococci.<sup>1, 4, 9, 12, 14, 15</sup> From theoretical points of view these resistant bacteria could exist as naturally occurring variants, they could arise as variants of normally susceptible strains as a result of contact with and adaptation to the drug, or they could arise as spontaneous genetic mutants. Whatever the explanation of this phenomenon, once sulfonamide-resistant variants appear they increase in prevalence in a sulfonamide-containing environment as a result of their greater fitness to survive. It is of interest to determine what light recent clinical and epidemiologic experience has shed on this problem.

Although methods to detect the development of sulfonamide resistance by other bacteria in vitro were known, attempts to demonstrate the resistance of hemolytic streptococci to sulfonamides, by the use of ordinary mediums containing sulfonamide inhibitors, were uniformly unsuccessful.<sup>3</sup> The need for a method of demonstrating sulfonamide re-

sistance in vitro became urgent with the failure of the mass chemoprophylaxis program in the armed forces in 1944. During that year Wilson<sup>11</sup> developed a technic that enabled one to determine the ability of hemolytic streptococci to grow in a semisolid medium free of sulfonamide inhibitor and containing respectively 0, 1, 5, 25 and 125 mg per 100 cc of sodium sulfadiazine. This test conclusively demonstrated the presence of sulfonamide-resistant strains of hemolytic streptococci, which were the cause of increasing numbers of upper respiratory infections while sulfonamide prophylaxis was being carried out in the armed forces.<sup>2, 4</sup>

After the first demonstration of sulfonamide-resistant Types 3, 17 and 19 Group A hemolytic streptococci during a program of mass chemopro-

phylaxis in the armed forces,<sup>2, 4</sup> it became essential to know if there were any resistant strains before this program was inaugurated in the Navy in December, 1943.<sup>1, 2</sup> This information could be obtained only by tests of cultures that had been preserved prior to this program of mass chemoprophylaxis. No sulfonamide resistance was demonstrated in over 100 of the strains of hemolytic streptococci preserved at the Rockefeller Institute Hospital prior to 1937.<sup>16</sup> Siegel<sup>17</sup> showed that 90 strains of Group A hemolytic streptococci isolated from scarlet-fever patients before 1938 were sensitive to the action of sulfadiazine. Sensitivity determinations on strains of hemolytic streptococci isolated from patients with scarlet fever<sup>12</sup> in the United States Navy prior to December, 1943, did not show any evidence of resistance. Most of these strains were Type 19, and some were isolated from patients who had been receiving small doses of sulfadiazine during a scarlet-fever epidemic in New York City.<sup>18</sup> It should be noted that strains of Type 19 later

appearing in the armed forces were resistant to sulfonamides. From this information it seems safe to conclude that before the program of mass sulfadiazine prophylaxis had been initiated in the armed forces in 1943 there were no known sulfonamide-resistant Group A hemolytic streptococci.

Rantz et al,<sup>14</sup> however, reported the results of testing strains of Group A hemolytic streptococci isolated in the Army from December, 1943, to April, 1944, and observed that some of the typed strains were more resistant than others — that is, that they grew in suspensions of 1 mg and 5 mg of sodium sulfadiazine per 100 cc. The authors were of the opinion that these strains were naturally resistant to moderate amounts of sulfadiazine and were the precursors of the more highly resistant strains such as Types 3 and 17, which later became established as epidemic, resistant strains. The possibility of transfer of these resistant strains to Army personnel by members of the Navy on chemoprophylaxis cannot be ruled out.

Several studies of streptococcal carriers treated with sulfadiazine to rid them of the carrier state are enlightening in demonstrating the possibility of the development of resistance under those conditions of treatment. Strains of hemolytic streptococci isolated from 40 patients before and after treatment with therapeutic doses of sulfadiazine did not show any evidence of the development of resistance to sulfadiazine.<sup>12</sup> Another study of 10 carriers treated with 1 gm of sulfadiazine daily for a ten-week period did not reveal any increase in sulfadiazine resistance of the post-treatment cultures as compared with the pretreatment strains.<sup>17</sup> Hamburger et al<sup>18</sup> treated 45 carriers of Group A hemolytic streptococci with 1 gm of sulfadiazine daily for four-day to fifty-day periods, with no development of sulfadiazine-resistant strains during the treatment period. So far as is known at present, no evidence of the development of resistant strains of hemolytic streptococci has been reported from any rheumatic fever patients who are receiving daily prophylactic treatment with sulfonamides.<sup>20</sup> Under the conditions of the studies cited above, no resistant strains of hemolytic streptococci developed.

The spread and epidemiologic problems that these resistant organisms presented in the armed forces have been summarized in previous reports.<sup>3-8, 16</sup> Although it was known that the civilian population was exposed to these resistant strains of hemolytic streptococci, no epidemics therefrom were reported until 1946, when an outbreak of Type 19 infections appeared in Cooperstown, New York.<sup>9</sup> Except for the Type 19 strains, resistant to 25 mg per 100 cc of sodium sulfadiazine, isolated during that study, none of the types showed any evidence of resistance. In the present report all strains, except the one resistant Type 19 strain, were susceptible to the action of sodium sulfadiazine. Apparently, there have been no problems of therapy in these resistant

streptococcal infections since they can be adequately treated with penicillin.<sup>21</sup>

The results of the present study of 167 strains of Group A hemolytic streptococci indicate that only one strain, which belonged to Type 19, was resistant to the action of sulfadiazine. This strain grew in a concentration of 25 mg of sodium sulfadiazine per 100 cc — the same concentration as the epidemic Type 19 strains that were prevalent in the armed forces. The source of this strain is not known, but it was probably introduced into this area by Army or Navy personnel. The possibility that this resistant strain is a naturally resistant variant cannot be ruled out, but the available information indicates that the resistant organism encountered in this study was the same as that in the armed forces.

The data of this study show that sulfonamide-resistant variants of Group A hemolytic streptococci did not arise in this area of Boston and its environs, where sulfonamides are used in the customary manner in the treatment of patients and where sulfonamide prophylaxis has not been widely employed.

From the accumulated evidence presented, it seems that conditions of mass sulfadiazine prophylaxis as they existed in the armed forces<sup>1, 2</sup> were conducive to the development of sulfadiazine-resistant strains of hemolytic streptococci. Regarding the conditions under which drug-resistant organisms can be expected to arise, one observer has postulated that "the infection shall be a common type providing very large numbers of micro-organisms within which a rare mutation has a chance to arise, and second — and this is the medically important point — that a large proportion of the potential hosts shall be treated with the drug in question."<sup>16</sup> To date these resistant strains have not presented any particular problem in civilian life and can be adequately treated by penicillin therapy. The possibility of the development of resistant strains of bacteria during large-scale mass prophylactic programs should be kept in mind, and such programs should be used only as an emergency measure.

## SUMMARY

Sulfonamide sensitivity determinations on 167 strains of Group A hemolytic streptococci, isolated from patients from Boston and surrounding suburbs, are presented. Only one strain, Type 19, was resistant to 25 mg per 100 cc of sodium sulfadiazine.

The pertinent literature regarding the development of sulfonamide-resistant hemolytic streptococci is reviewed.

## MEDICAL PROGRESS

### THE ROLE OF PLEUROPNEUMONIA-LIKE ORGANISMS IN GENITOURINARY AND JOINT DISEASES (Concluded)\*

LOUIS DIENES, M.D.,† MARIAN W. ROPES, M.D.,‡ WILLIAM E. SMITH, M.D.,§ SARABELLE MADOFF AND WALTER BAUER, M.D.¶

BOSTON

THE high incidence of acute joint disease in male patients with positive prostatic cultures, in addition to the knowledge that animals infected with L organisms frequently have arthritis, suggests that pleuropneumonia-like organisms play a role in producing the joint disease in the patients. The hypothesis that this organism is the cause of the arthritis is somewhat supported by the fact that in 2 cases of Reiter's syndrome (as Case 11) L organisms were cultured from the knee-joint fluid. However, no L organisms were found in the synovial fluids in the other 11 cases in this series in which a search for these organisms was made.

In women, a relation between the presence of the L organism in the genital tract and the development of joint disease was not so apparent. Among 58 women yielding positive cultures in the original series, only 9 had joint complaints. One of these patients also had gonococci in the cervical cultures. Two other cases were arbitrarily introduced into the series since they had rheumatoid arthritis and formed part of a group of 12 female patients with

rheumatoid arthritis in whom routine examination of cervical cultures for L organisms was made. Five of the 6 remaining patients had bad swelling and pain of long duration in various joints. The other patient (Case 10) had an acute arthritis that had developed two weeks after marriage. Her husband (Case 9) also developed joint symptoms eight weeks after marriage, and L organisms were found in the prostate at that time. In view of the high incidence of L organisms in the female genital tract (26 per cent) and the relatively low percentage of joint disease in female patients with positive cultures, there is no definite evidence of a relation between the L organism and the joint disease in these cases. However, the observations in the married couple suggest not only that the joint involvement was related to the L organism but also that certain strains have a greater tendency than others to produce joint disease. Further suggestion of a possible relation between the L organism and joint disease in women was furnished by 2 other patients, seen since the original series was completed, who had acute arthritis at the time cervical cultures were positive for L organisms and negative for gonococci.

Until further information is available concerning the pathogenicity of the various human strains of pleuropneumonia-like organisms, it is difficult to conclude whether or not the conditions produced by these organisms are contagious. Certain findings suggest that they are. The wives of 5 of the men from whose prostates L organisms were cultured

were studied, and in 2 cases *L* organisms were found in the cervical cultures. In 1 case—that of the married couple discussed above—both husband and wife developed acute arthritis soon after marriage. Beveridge, Campbell and Lind<sup>9</sup> cultured pleuropneumonia-like organisms from 3 of 11 women from whom men had contracted nonspecific urethritis. The fact that the genitourinary, joint or eye symptoms in at least 7 of the men with positive cultures in the present series developed within a few days after sexual exposure suggests that the disease is venereal in some cases. However, in many cases no history of exposure was obtained. The possibility that the gastrointestinal tract was the portal of entry in some cases is suggested by the fact that at least 6 patients had diarrhea just before or at the onset of the disease.

The treatment of diseases produced by pleuropneumonia-like organisms is still in an experimental stage. In rats and mice these diseases have been shown to be prevented or effectively treated in a high percentage of cases by gold compounds<sup>22, 23</sup> and by streptomycin.<sup>24</sup> Penicillin has not been effective in animals.<sup>25</sup> Pleuropneumonia-like organisms are not sensitive in vitro to sulfonamides or penicillin, but the growth of some strains has been found to be inhibited by streptomycin in a concentration of 20 microgm per cubic centimeter.<sup>17</sup> In the present series gold was used in only 1 patient (Case 4) and was ineffective. None of the patients treated with sulfonamides or penicillin showed any improvement in the genitourinary or joint symptoms. Streptomycin was used in 8 patients in whom the infection was limited to the genitourinary tract (see Cases 4 and 5), including 4 cases of cystitis, in 1 patient with acute arthritis associated with urethritis, and in 5 patients with Reiter's syndrome (Case 12).<sup>\*</sup> In 7 of the 8 cases of genitourinary-tract infection there was rapid disappearance of symptoms during treatment, and cultures became negative for *L* organisms. The eighth case, in a patient who had had urethritis for sixteen years (Case 4), showed only a transient improvement in symptoms, and the pleuropneumonia-like organisms did not disappear from the urethral cultures. In the patients with acute arthritis or Reiter's syndrome, there was improvement in symptoms during and immediately after treatment. However, evidence of joint inflammation persisted for weeks, and the sedimentation rates remained elevated. In none of the cases were *L* organisms cultured after treatment. Streptomycin therapy did not prevent recurrences of the disease in Case 12. The results of streptomycin therapy were not conclusive but indicate that the drug is probably effective in most cases of uncomplicated genitourinary-tract disease due to pleuropneumonia-like organisms. In Reiter's

syndrome the results were sufficiently suggestive to warrant further trial of this therapy.

### CASE REPORTS

The following brief abstracts include characteristic cases from the various groups.

**CASE 1 (M G H 22349) †** A 33-year-old female research worker who handled rats almost daily and who gave no history of previous genitourinary disease noted sudden onset of tenderness and swelling of the right labium majus 10 days after marriage. On examination an abscess of Bartholin's gland was found. Cervical smears were negative for gonococci. Excision of the abscess *in toto* was performed, and cultures were made at the operating table from the center of the abscess, which contained creamy-yellow pus. These cultures yielded an abundant growth of *L* organisms in pure culture. Streptobacilli or gonococci could not be demonstrated by smear or culture. The patient recovered uneventfully.

**CASE 2** An 18-year-old single girl noted the onset of profuse vaginal discharge 4 days after intercourse. On examination there was an acute vaginitis, with a fiery red mucosa and yellow purulent exudate. Cultures of this exudate yielded a pure growth of *L* organisms. Gonococci could not be demonstrated by smear or culture. The vaginitis cleared up within 1 week.

### Patients with Urethritis and Prostatitis

**CASE 3** A young married man, 36 hours after extramarital exposure, observed slight urethral discharge. On examination no discharge was apparent, but the prostate was found to be swollen and painful. In the culture made from a sample of urine immediately after prostatic massage many *L* colonies but no gonococci were seen. A second culture 10 days later was negative for *L* organisms and for gonococci. The subsequent clinical course is not known.<sup>‡</sup>

**CASE 4 (M G H 492207)** A 35-year-old married man was admitted to the hospital because of persistent urethral discharge. Sixteen years previously, 3 days after intercourse, he had developed a yellowish urethral discharge and inguinal lymphadenopathy. The discharge had not changed throughout the 16 years despite many types of treatment, including sulfonamides, penicillin and numerous kinds of local therapy. Cultures had always been negative for gonococci, but during the year before admission had been positive for pleuropneumonia-like organisms on several occasions. Examination was negative except for slight urethral discharge and enlargement of the prostate. The patient was treated with streptomycin, in a dosage of 4 gm a day, for 1 week. The discharge disappeared after 1 day of treatment, but cultures of the prostatic secretion continued to show many colonies of *L* organisms. Ten days after treatment was stopped the discharge returned and has persisted for the past 11 months. During this interval he has been treated with myocrisine, receiving 325 mg in 5 weeks without effect.

### Patients with Cystitis

**CASE 5 (M G H 532255) §** A 26-year-old single man was admitted to the hospital because of frequency of urination and terminal hematuria. Three years before admission he had had urethral discharge and frequency of urination lasting for several weeks. Subsequently, there had been repeated recurrences of burning and frequency. Two weeks before admission he had first noted blood in the terminal portion of the urine. Cultures had always been negative for gonococci. Examination was negative except for the fact that the prostate was rather soft. The urine was loaded

\*We are indebted to the Committee on Chemotherapeutics of the National Research Council for the streptomycin used during most of this study and to Merck and Company for the streptomycin now being employed for test of its efficacy in the treatment of infections due to pleuropneumonia-like organisms.

†We are indebted to Dr. L. Parsons, of the Massachusetts General Hospital for permission to report this case. Reference to this patient has been made by Dienes and Edsall.<sup>2</sup>

‡This was a patient of the late Dr. Richard F. O'Neil.  
§We are indebted to Dr. Fletcher H. Colby, of the Massachusetts General Hospital, for permission to include this case which has also been reported by Kane and Foley.<sup>26</sup>

with erythrocytes and leukocytes. Three routine cultures of urine showed no growth but cultures on boiled blood ascitic agar contained numerous colonies of pleuropneumonia-like organisms. The patient was given 2 gm of streptomycin daily for 4 days and 1 gm daily for the following 5 days. Cultures became negative for L organisms after 3 days of treatment, and the urinary sediment showed only rare cells. There has been no recurrence of symptoms in the subsequent 14 months.

### *Patients with Chronic Arthritis*

**CASE 6 (M G H 534532).** A 32-year-old married man was admitted to the hospital because of severe pain and redness of the right eye of 1 week's duration. Seven years before admission he had had a nrethral discharge, smears from which were reported to contain gonococci. Five years later he had begun to notice migratory pains in the hips, right knee, neck, and lower back. Six months before admission the right knee became swollen and painful. Examination showed an iritis of the right eye with marked chorioretinitis, an effusion in the right knee and slight tenderness and induration of the prostate. Prostatic cultures showed a moderate growth of L organisms and of non-hemolytic streptococci. The arthritis subsided in 3 months but the iritis still persists at the end of 11 months. During this period central chorioiditis has developed and has been treated with fever induced by intravenous injection of typhoid vaccine. Prostatic cultures have remained positive for L organisms.

It is impossible to determine whether or not the various features of this patient's disease are interrelated in any way.

### *Patients with Acute Arthritis without Eye Involvement*

**CASE 7 (M G H 352561).** A 47-year-old married man noted burning on urination 2 or 3 days after sexual exposure. One week later he developed stiffness of the knees, right wrist and right shoulder. The stiffness of the knees persisted and 3 weeks later the left wrist became very swollen, red, hot and tender. These symptoms subsided in 2 or 3 days but the right wrist became involved. Examination on the following day showed tenderness, increased heat and pitting edema of the right wrist and the dorsum of the right hand and a moderate-sized effusion in the left knee which was warm and tender. The prostate was tender and boggy. Culture of the prostatic secretion showed numerous colonies of L organisms and *Staphylococcus aureus* but was negative for gonococci. All symptoms subsided in 2 weeks though the sedimentation rate remained elevated. There was no recurrence of symptoms during the subsequent 2 years.

**CASE 8 (M G H 315068).** A 29-year-old single man had had a urethral discharge 6 months before admission. Soon thereafter he had noted pain and swelling of the left knee, left third toe and right third finger. There had been no response to sulfonamide therapy but the symptoms subsided slowly over the course of 4 months. Two weeks before admission the nrethral discharge recurred and pain developed in the right hip, left shoulder and tarsometatarsal joints on both sides. The patient had had a urethritis said to be of gonococcal origin, 8 years before admission. On examination at the time of admission the left knee contained a moderate-sized effusion and was tender. The prostate was large and boggy. Cultures of prostatic secretion showed abundant L colonies but no gonococci. The patient was again treated with sulfonamides with no effect. The symptoms gradually disappeared over the course of 2 months. Cultures of prostatic secretion were negative for L organisms 4 years later.

**CASE 9 (M G H 291517).** This 38-year-old man the husband of the patient in Case 10 was seen in 1942, when he had been married 8 weeks. He had had urethritis in 1929 and again in 1934. Gonococci were said to have been seen in smears during both these attacks, but they could never be demonstrated at any time thereafter. In 1937, 1940 and 1941 he had been treated for chronic prostatitis smears showing pus cells but no gonococci. In March 1942 the patient was admitted to the hospital for painful swelling of the left wrist of 3 days duration. On examination the prostate did not feel abnormal but massage yielded fluid containing 20

30 pus cells per high-power field. Cultures yielded no gonococci but gave an abundant growth of L organisms streptococci and diphtheroids. Four months later pain and swelling developed in the right elbow, persisting for 9 months. During this episode the prostate was found to be boggy and the vesicles were tender. Prostatic cultures yielded occasional L organisms and an abundant growth of bacteroides nonhemolytic streptococci and *Staph. albus*. Four years later the patient had recurrent attacks of pain in the left flank, and x-ray study showed a stone in the lower end of the left ureter. At the time of admission for removal of the stone the urine was cultured but showed no growth of pleuropneumonia-like or other organisms.

**CASE 10 (M G H 348216).** A 30-year-old woman, the wife of the patient in Case 9, was admitted to the hospital in March, 1942, 3 days after her husband's first admission. She gave no history of genitourinary disease and had been well until 6 weeks before entry when 2 weeks after marriage she developed stiff swollen knees. There was no redness or heat about the knees and the swelling caused only moderate discomfort. No other joints were involved and there was no fever and no constitutional symptoms. Pelvic examination revealed a slight cervical discharge, cultures of which yielded a pure growth of L organisms. No organisms were found in gram-stained or Giemsa-stained films of the joint fluid, and none could be recovered in culture. The patient was discharged unimproved after 1 week. The involvement of the knees gradually subsided during the following year.

### *Patients with Acute Arthritis with Eye Involvement (Reiter's Syndrome)*

**CASE 11 (M G H 440804)\*.** A 26-year-old single man developed a purulent urethral discharge 36 hours after sexual exposure. He was treated with sulfathiazole and sulfadiazine, but the discharge persisted and 3 weeks after onset he noted burning, frequency, urgency and terminal hematuria. Approximately 5 weeks later bilateral conjunctivitis appeared and within a few days he complained of pain in the lumbosacral region as well as pain and swelling of the right ankle, right shoulder, left elbow and left knee. On examination 3 days later, the temperature was 100.4°F with slight conjunctival injection and swelling and tenderness of the right ankle, left knee and right sternoclavicular joint. The nrethral discharge had subsided but a catheterized specimen of urine was loaded with white cells. Cultures of the urine and prostatic secretion showed an abundant growth of L organisms and a few colonies of staphylococci but were negative for gonococci. Two colonies of L organisms were found in the culture of fluid from the left knee. At the time of discharge, cultures of the urine showed only a few L organisms. The patient was treated with 120,000 units of penicillin with out effect but all symptoms subsided slowly during the course of 2 months.

**CASE 12 (M G H 255127).** A 26-year-old single man had had pain in the right ankle and right knee and slight urethral discharge for 2½ weeks before admission. Examination revealed marked swelling of the right knee with an effusion and moderate swelling of the right ankle. The prostate was slightly enlarged and boggy. Three weeks later an iritis developed in the left eye. Culture of the prostatic secretion showed abundant growth of L organisms and many streptococci and colon bacilli but was negative for gonococci. The patient was treated with sulfathiazole and penicillin without effect. The symptoms gradually subsided during the course of 6 months. He had had a similar attack 4 years previously with bilateral conjunctivitis and keratitis, purulent urethral discharge and arthritis. There had been a second attack 1 year later, manifested by urethral discharge, balanitis and prostatic bilateral conjunctivitis and keratitis and arthritis.

After the third attack described above had subsided the patient remained entirely well except for occasional episodes of slight conjunctivitis until 1 year after discharge when prostatic massage was performed. Culture of the prostatic

\*We are indebted to Dr. Fletcher H. Colby of the Massachusetts General Hospital, for permission to report this case, the first urinary secretion of which have been reported by him.

†These first two attacks have been reported elsewhere.

secretion was negative for L organisms. Two days later, he noted slight urethral discharge and 1 week later developed bilateral conjunctivitis. During the following week, the right hip and both knees became painful. On examination the conjunctivas of both eyes were markedly inflamed. The right hip was painful, and both knees contained effusions. Prostatic cultures showed an abundant growth of L organisms and a few staphylococci but no gonococci. The urethritis and conjunctivitis subsided in 2 weeks, but during the following 2 months, he continued to have intermittent attacks of pain, swelling and tenderness of wrists, knees and left first metacarpophalangeal joint. Roentgenograms showed moderate decalcification of the bones around the knees and wrists. At the end of 2 months, streptomycin was obtained, and the patient received 21.5 gm. in 6 days. Subsequently, he had no further recurrence of joint symptoms though the sedimentation rate remained slightly elevated for 3 months.

Thereafter, he continued to feel well until 3 months later, when he noted stiffness and swelling of the left knee. Four days later there was recurrence of slight urethral discharge and on the following day slight conjunctivitis. On examination 5 days later, the left knee and the interphalangeal joint of the right first toe were hot, red, very painful and swollen. There was a severe conjunctivitis, with purulent discharge, and a slight urethral discharge. Cultures of the urethral discharge and of the urine showed a moderate growth of L organisms and a few colon bacilli and *Staph. albus* and *Staph. aureus*. Roentgenograms showed persistence of slight decalcification of the bones around the knees. The patient was treated with streptomycin in a dosage of 4 gm. a day for 13 days. The urethritis and conjunctivitis subsided within 1 week, but swelling of the left knee persisted for 2 months. The sedimentation rate has remained slightly elevated for the past 5 months.

### DISCUSSION

The observation that human beings may harbor organisms belonging to a group that includes several important animal pathogens is in itself interesting. Interest is heightened by the fact that these pleuropneumonia-like organisms appear to be pathogenic to human beings. The most definite indication of pathogenicity has been obtained from the study of male patients. The fact that all the patients in this series had urethritis, prostatitis or cystitis suggests that the organism is pathogenic for the genitourinary tract. Most impressive were the patients with cystitis, such as Case 11, in whom the L organisms were present in pure culture for a long period and decreased markedly or disappeared from the urine as the clinical symptoms subsided. Further indication of the pathogenicity was obtained from one of the patients with Reiter's syndrome (Case 12). L organisms were cultured from the prostatic secretion at the onset of three separate attacks of the disease and were not found in the interval between the episodes.

The presence of acute joint involvement in 27 of the 58 men with positive cultures for L organisms suggests pathogenicity for synovial tissues as well as the genitourinary tract. In 2 patients with Reiter's syndrome, organisms were cultured from the synovial fluid. This association with joint disease is of particular interest because joint involvement is a common feature of the diseases produced by the pleuropneumonia group of organisms in animals.

The evidence of pathogenicity gained from the study of female patients is more equivocal. The relatively high incidence of L organisms in the

female genitourinary tract suggests that they are part of the normal bacterial flora in this location. On the other hand, their presence in various inflammatory processes of the genitourinary tract either in pure culture or in much greater abundance than other bacteria suggests that they are at times pathogenic.

In evaluation of the evidence gathered to date it should be remembered that some strains are presumably not recovered by the present methods, and that the strains isolated probably belong to more than one species and differ in their pathological significance. The fundamental biologic study of the organism obtained from human beings is still in a primitive stage. The cultural methods, which at present are the only means of recognition, are probably inadequate. Attempts are now being made to develop biologic methods, such as serologic and skin tests. The need for a more detailed study of the properties of the various strains, especially their serologic characteristics and their pathogenicity, is indicated by the observations that attest to their ability to cause disease in human beings.

Further difficulty in evaluating the role of pleuropneumonia-like organisms arises from the fact that some of the bacteria commonly found in human beings grow in an L variant form under certain cultural conditions, as in the presence of penicillin. Because of this difficulty, the 8 male patients with severe urinary-tract infection in whom L organisms were found only after the growth of other bacteria was suppressed either by addition of penicillin to the medium or by treatment of the patient with penicillin or streptomycin have not been included in the present series. It is impossible to assess the significance of the L organisms in these cases. It seems probable that they represent one of the many organisms that together cause the urinary-tract infection. However, they may be variant forms of the other bacteria present in the inflamed urinary tract.

### SUMMARY

The properties of pleuropneumonia-like organisms (L organisms) and the methods used for their isolation and identification are briefly described.

Pleuropneumonia-like organisms were present in 58 of 222 routine specimens (26 per cent) from the uterine cervix and vagina and may be part of the normal bacterial flora in these locations. Suggestion of possible pathogenicity, however, was provided by their recovery from inflammatory processes of the female genital tract.

Pleuropneumonia-like organisms were found in only 6 of 71 routine specimens from the male genitourinary tract. Evidence of their pathogenicity was more definite than that in women, since all 58 patients of this series from whom positive cultures were obtained had urethritis, prostatitis or cystitis. In 6 of the 9 cases in which the

infection extended into the bladder the organisms were obtained in pure culture from the urine. Gonococci and L organisms were found simultaneously in only 2 male patients.

Material from other sources, including the respiratory and gastrointestinal tracts and cerebrospinal fluid, was examined by similar methods but with negative results except in synovial fluids from 2 patients with Reiter's syndrome.

Eighteen of the 58 male patients with genitourinary-tract infections had an acute type of arthritis when the cultures were positive for L organisms. Nine of these men had simultaneous urethritis, conjunctivitis and arthritis, the syndrome characteristic of so-called Reiter's disease. In 1 patient L organisms were found in the prostate during three attacks of the disease.

These observations indicate that pleuropneumonia-like organisms have pathogenic activity in the genitourinary tracts of men and women and may be related etiologically to an acute infectious type of arthritis and to Reiter's syndrome.

We are indebted to the following physicians for permission to include cases in this series: Drs. F. Albright, J. D. Barney,

W. W. Beckman, R. Chute, F. H. Colby, L. W. Kane, S. B. Kelley, S. McGinn, L. S. McKittrick, J. V. Meigs, L. Parsons, C. L. Short and H. L. Snyby of the Massachusetts General Hospital; Dr. R. L. Berg of the United States Naval Hospital, Chelsea; Drs. T. H. Flynn and A. H. Mayhew of the United States Marine Hospital, Brighton; Dr. J. A. McLaughlin, Naval Air Station, Squantum; Dr. T. A. Warthin, Veterans' Administration Hospital, West Roxbury; and Cushing Veterans' Administration Hospital, Framingham.

Eight of the cases of this series have been included in other papers.<sup>2, 3, 7, 8, 9, 10</sup> Seven others will be reported by Berg and McLaughlin.

## CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

### Weekly Clinicopathological Exercises

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., Editor

BENJAMIN CASTLEMAN, M.D., Associate Editor

EDITH E. PARRIS, Assistant Editor

### CASE 34161

#### PRESENTATION OF CASE

A three-and-a-half-month-old male infant entered the hospital because of persistent diarrhea.

The birth weight was 6 pounds, 3 ounces, and a statement was made that the baby was blue at birth. However, he gained weight at a normal rate, ate well, and seemed normal in every way except that when he cried or breathed rapidly some cyanosis appeared. There had never been any convulsions, hematuria, vomiting or jaundice.

Four weeks prior to entry the patient developed a cough and coryza, and had several bouts of what were said to be projectile vomiting. Four days later he was taken to another hospital, where a diagnosis of bronchopneumonia was made. X-ray films at that time showed the heart to be to the right of the sternum and an additional diagnosis of congenital heart disease was made. He remained in the hospital and ten days before admission to this hospital

he developed a persistent and moderately severe diarrhea (ten to twelve bowel movements per day). Several of the other infants on this ward also developed diarrhea at about the same time. Five days before admission the diarrhea became much severer, and penicillin therapy was started. Because of the persistent diarrhea the patient was transferred to this hospital.

Physical examination revealed a marasmic and cyanotic infant. He appeared to be fairly well hydrated. Cyanosis was present to a mild degree but was considerably intensified when the patient cried. The chest was clear to percussion and auscultation. The heart was percussed to the right of the sternum and the point of maximum impulse was in the fifth interspace 4 cm. to the right of the sternum. The rhythm was normal, and the rate was 140. There was a soft, Grade II systolic murmur heard best in the third interspace to the left of the sternum.

Examination of the blood disclosed a red-cell count of 4,740,000, with a hemoglobin of 14 gm., and a white-cell count of 7500, with 88 per cent neutrophils. The urine was normal. Blood cultures were negative, and cultures of the stool showed no significant organisms. A blood Hinton test was negative. A tuberculin test in a dilution of 1:1000 was negative.

Soon after admission the number of daily bowel movements decreased markedly, until they became normal. On the third hospital day the child had an episode of severe cyanosis associated with vigorous respiratory activity. The trachea was suctioned, and much thick white mucus was recovered. The patient recovered entirely within fifteen minutes.

The next day a swallow of lipiodol was given, and x-ray examinations showed no evidence of an esophagotracheal communication. The lipiodol passed down the esophagus into the stomach, which lay in normal position on the left side. There was no evidence of constriction of the esophagus. There was a slight indentation opposite the arch of the aorta, which seemed to indicate that the aorta descended on the left side. There was also a ques-

FIGURE 1 *Roentgenogram, Showing the Apex of the Heart in the Right Midclavicular Line*

tionable filling defect just above the aortic arch as seen on the anteroposterior view. The lung fields were essentially clear, without evidence of active disease. The pulmonary vascular markings throughout seemed to be decreased. The apex of the heart lay in the right midclavicular line (Fig. 1).

On the sixth hospital day the patient had a cyanotic episode, much the same as the previous one. However, suction did not relieve the attack, and a laryngoscope and then a bronchoscope were passed and a small amount of mucus was removed. After oxygen had been administered for some time the patient was able to breathe somewhat more easily, but there was still considerable forcefulness to the respiratory movements and some retraction of the interspaces. Because of the presence of bubbling rales at the lung bases sulfadiazine and penicillin therapy were instituted. An electrocardiogram was interpreted as being consistent with dextrocardia. The spinal fluid was not remarkable. Bilateral sub-

dural taps were done on the eighth day, without return of fluid. On the fourteenth day the temperature began to spike up to 102°F. The white-cell count was 10,900. Physical examination showed a questionable decrease in the percussion note over the left lower lobe. Because he was not taking his feedings very well, the patient had been started on stomach-tube feedings. On the twentieth hospital day, immediately after one feeding, he began to cough, became cyanotic, breathed very rapidly, and died, despite attempts at suction and artificial respiration.

#### DIFFERENTIAL DIAGNOSIS

DR FRANCIS McDONALD Will Dr Wyman please demonstrate the films?

DR STANLEY M WYMAN The best demonstration of the esophagus is shown by the opaque tube, which extends through the esophagus into the stomach on the right side. The heart is seen on the right.

DR McDONALD "There was a slight indentation opposite the arch of the aorta, which seemed to indicate that the aorta descended on the left side."

DR WYMAN That is suggested on one of the spot films. However, a better look at the plain film with the tube in place shows a considerable shadow to the right of the esophagus and trachea, which makes me think that the aorta actually descends on the right side rather than on the left. I think that the observation of the left-sided aorta is perhaps inaccurate. The filling defect I cannot identify. There is good filling of the esophagus in this portion. I can detect no true abnormality from the films, which are not satisfactory and are noncontributory. The chest films show that the heart is in the right side of the chest, with the apex pointing to the right. The heart is not grossly enlarged. The pulmonary-vascular shadows are decreased in prominence. There is some multiple increased density in the left lung field medially. I should think that this was some sort of pneumonic process. It is seen on the other films consistently. We can therefore say that the heart is not grossly enlarged and lies on the right side (a dextroposed heart), the pulmonary vascular shadows are decreased in prominence and there is presumably some congenital anomaly.

DR RONALD C SNIFFEN The liver is on the right side?

DR WYMAN Yes, it is on the correct side.

DR McDONALD Was the mucus removed by the bronchoscope cultured?

DR CHARLES U LOWE It was cultured and yielded *Staphylococcus aureus*.

DR McDONALD I would welcome expert advice on the electrocardiogram.

DR SNIFFEN I do not believe there is anyone here who can give it.

DR McDONALD It sounds like a relatively clear-cut interpretation. About the only mistake that might be made is transposition of the arm electrodes.

I am not a cardiac expert, so that for the interest of the group, I shall quote from Taussig's\* book.

Lead I is in the mirror image of normal. Leads II and III replace each other. In Lead I both P waves and the T waves are normally inverted and the principal deflection of the QRS complex is downward. The findings in Lead III are those usually seen in Lead II and the form of deflection in Lead II is similar to that seen normally in Lead III.

DR. SNIFFEN The interpretation of the electrocardiogram was as follows: "The tracing is consistent with dextrocardia and inverted Lead I and interchanged electrodes 2 and 3 give normal axis and T waves."

I might say that the child did much better in an oxygen tent than is indicated in the record.

DR. McDONALD It seems as if we have two main categories for diagnosis here. One is infection. We have an infant in an age group that is immunologically immature, subject to invasion by colon bacilli, staphylococci, influenza bacilli and other organisms, in addition to the usual streptococcal and pneumococcal invaders of the respiratory tract. It is extremely important in this age group to obtain blood cultures (using pour plates and broth flasks) and cultures of coughed-up secretions to obtain a precise idea what the organism is and to govern therapy accordingly. This patient was given sulfadiazine and penicillin, probably on that basis. *Staph. aureus* was obtained on one attempt and cannot be passed off as a contaminating organism, as it frequently may in an adult group. *Staphylococcus* may be an invading agent in this age group. The cough, the dyspnea, the course and the x-ray findings, which might possibly be consistent with an early atelectasis or bronchiectasis as well as pneumonia, make me conclude that the baby did have pneumonia. The second diagnosis is a definitely proved cardiac abnormality. I believe that we can take the word of Dr. Wyman that displacement of the heart was not likely from any of the physical findings or x-ray evidence. The electrocardiogram of dextrocardia is a conclusive finding. The presence of dextrocardia without situs inversus markedly increases the likelihood of associated anomalies. We can therefore assume that, in addition to the dextrocardia, either there were anomalies of the heart itself or, if by chance the aortic arch was on the left side, there was a good likelihood of anomalies of the vessels at the base of the heart. As may be seen in this case, the heart is twisted around, with the aortic arch where it should be normally, with the corresponding difficulty in readjustment of the vessels at the base. In addition to the diagnosis of dextrocardia without situs inversus I shall say question of pulmonary stenosis, question of single ventricle and question of anomaly of vessels at the base of the heart.

DR. SNIFFEN You took care of this patient, Dr. Lowe. Have you anything to add?

DR. LOWE There are two things that might be clarified—first of all the difficulties with inspiration, the cyanosis usually followed feeding, which strongly suggested vascular anomaly at the base of the heart. The second point is that it was obvious that oxygen helped the child, which is unusual in children with cyanotic heart disease.

DR. RICHARD SCHATZKI Is it not likely if a baby is short of breath that feeding usually makes the difficulty worse?

DR. LOWE The child was not short of breath normally. The extreme attacks described in the record

FIGURE 2. Drawing of the Heart and Great Vessels, Showing Persistent Truncus, Patent Interventricular Septum, Tricuspid Semilunar Valve, Pulmonary Arteries from Truncus, Persistent Fifth Aortic Arch on the Left and Right Sided Aorta.

occurred seven times while the child was in the hospital, and the last one was fatal. Dyspnea was not part of the general picture.

#### CLINICAL DIAGNOSES

Asphyxiation due to aspiration of feeding  
Persistent double aortic arch  
Dextrocardia  
Pneumonia  
Congenital heart disease

#### DR. McDONALD'S DIAGNOSES

Pneumonia  
Dextrocardia  
? Single ventricle.  
? Pulmonary stenosis  
? Anomaly of vessels at base of heart

#### ANATOMICAL DIAGNOSES

Right-sided aorta  
Persistent truncus arteriosus  
Patent interventricular septum  
Persistent fifth aortic arch on left  
Acute purulent bronchitis with early bronchopneumonia

\*Taussig, H. B. *Congenital Malformations of the Heart*, 618 pp. New York: Commonwealth Fund, 1947.

## PATHOLOGICAL DISCUSSION

DR SNIFFEN At the time of death the patient was somewhat emaciated and cyanotic. The abnormal findings were confined to the heart and lungs. In the lungs there was a generalized purulent bronchitis most marked in the left lower lobe. This was accompanied by a mild peribronchial inflammatory infiltration involving the alveolar walls and septums. On the left side there was a fibrinous and fibrous pleurisy without effusion. A small amount of mucus and aspirated gastric contents were found in the trachea and major bronchi. The apex of the heart lay in the right midclavicular line. The pericardium and myocardium were normal,

arteries, which were not over 1 mm in diameter. The ductus arteriosus was not patent. Then, as one proceeded distally along the arch of the aorta, just beyond the left pulmonary vessel, an arterial trunk left the aorta. This trunk divided immediately into two branches, the first giving rise to the left subclavian and internal carotid arteries, and the second to the left external carotid artery. The next aortic branch was the right common carotid artery, with its external and internal divisions, and the last major vessel to leave the aortic arch was the right subclavian artery.

We believe that these structural abnormalities were the results of the disintegration of the first

FIGURE 3 Drawing, Showing Disintegration of the First Four Aortic Arches on the Left, with Persistence of the Fifth Aortic Arch

the latter measuring 4 mm in each ventricle. The heart was slightly enlarged.

The dissection of maldeveloped hearts is confusing, since minor structural variations change the interpretation of the developmental abnormalities a great deal. I shall demonstrate several diagrams so that I will not become snarled in the mechanics of the arterial abnormalities.

The first is a drawing of the heart and great vessels in this child (Fig 2). The heart showed a persistent truncus, and as might have been expected with this anomaly, there was a defect in the membranous septum between the ventricles. The truncus overlay both ventricular chambers, but mainly the right ventricle. The outlet was guarded by three normal semilunar valve cusps of equal size. The coronary vessels followed the usual course. There was a right-sided aorta. The first branches to arise from the truncus were two minute pulmonary

four aortic arches on the left side, with persistence of the fifth aortic arch (Fig 3). The reason for this opinion is the fact that the main trunk on the left side was very short. If it were long, we could be confident that the fourth arch had persisted after the disintegration of the first three arches. Furthermore, this main trunk arose immediately distal to the left pulmonary artery. On the right side the fourth arch and dorsal aorta had persisted to form the main arterial trunk.

The formation of three equal semilunar cusps in the truncus is difficult to understand. One would expect four cusps of equal size or unequal size or three unequal cusps. In fact the truncus had the structure of a normal aorta.

As a sidelight, the left lung was divided into three lobes, and the right lung had only two lobes.

No constrictions were found in the esophagus, and the abdominal organs were in the normal position.

## CASE 34162

## PRESENTATION OF CASE

A forty-eight-year-old chauffeur entered the hospital because of pain in the right elbow.

One year before entry the patient had a painful right upper arm for a few weeks following a strain in breaking a fall. He recovered completely from this episode, however, and remained asymptomatic until one month before entry, when he slipped and twisted the right arm while shoveling snow. He immediately sustained severe pain around the elbow, with radiation to the outer aspect of the right shoulder. The pain gradually subsided and disappeared a week later, when he first noted swelling of the "muscles" just above the elbow. Two weeks before entry physical examination and x-ray studies demonstrated a "tumor" of the lower humerus. One week later he slipped and fell and felt a crack in the arm, with resulting severe pain. X-ray films were taken, the arm was splinted, and he was sent to this hospital.

His father had died of carcinoma of the liver, and an uncle had carcinoma of the stomach.

The patient allegedly had enjoyed excellent health and denied weight loss, systemic symptoms, previous trauma or bone disease.

Physical examination revealed a well developed and well nourished man with moderate pitting edema below the lower third of the humerus, a swelling around the elbow and a soft-tissue mass, 2.5 by 5 cm., above the medial epicondyle, in the region of which there seemed to be some abnormal mobility. There was no discoloration of the skin and no evidence of motor or sensory impairment. A few firm, nontender lymph nodes (0.5 to 1.0 cm in diameter) were palpated bilaterally in the groin. No abdominal masses or chest abnormalities were demonstrated.

The temperature was 98°F, the pulse 76, and the respirations 15.

Examination of the blood showed a hemoglobin of 15.1 gm per 100 cc and a white-cell count of 11,400, with 79 per cent neutrophils. Urinalysis was negative. No Bence-Jones protein was found.

X-ray films of the right humerus demonstrated a destructive process 10 cm long in the distal third through the entire thickness of bone but with no spicule formation, no new-bone formation, and no periosteal elevation, there was a pathologic fracture through this area. The medulla above the lesion had some irregular areas of mottling, and the cortex appeared roughened (Fig 1). Scout films of the chest, spine, pelvis, left arm and both legs were normal.

An operation was performed.

## DIFFERENTIAL DIAGNOSIS

DR CLIFFORD C. FRANSEEN. In the differential diagnosis of any suspected bone tumor, Dr Channing Simmons has taught us to review the history and

the signs and symptoms from three aspects: infectious, metabolic and neoplastic. The age (forty-eight years) is important to consider, as it is in any case of suspected bone tumor, and I shall deal with this later. This man either led a precarious existence or was very clumsy, because he suffered so many injuries from falls. Possibly, a neurologic examination would have thrown some light, but we do not have this information.

Let us consider infectious lesions first. With respect to osteomyelitis, the temperature was normal, and there was no suggestion of local inflammation. The record does not suggest a chronic inflam-

FIGURE 1

matory lesion, such as Brodie's abscess, especially by x-ray study. There was a slight elevation of the white-cell count, but little else to suggest that this process had arisen on the basis of osteomyelitis. In the latter lesions, also, enough reactive new-bone formation usually accompanies the osteomyelitis so that pathologic fracture is uncommon.

Syphilis must be considered only because it can simulate practically any bone lesion. The blood Hinton test is not given. We do not know whether or not it was taken, but, of course, it should be included in any study of a bone lesion. Syphilis, as a rule, produces considerable periosteal reaction, which was minimal or absent in this case. Tuberculosis can only be mentioned—we cannot rule it in or out in this case except for the statistical rarity of an isolated lesion in the humerus, especially since the chest film was normal.

We must consider the neoplastic group of diagnoses more seriously. The character of the destruction suggests that this was a neoplastic lesion, and probably a malignant one. Benign tumors that should first be considered are lesions such as bone cysts. They usually occur in the young age groups, and usually the first knowledge of their presence is the occurrence of pathologic fracture, unless they are picked up incidentally by an x-ray examination. It would be unusual for a man of this age to have one. A giant-cell tumor may remotely be suggested by the x-ray film, but the site in the bone is not a usual one. Perhaps we should see the x-ray films, since their interpretation becomes more important from now on.

DR STANLEY M. WYMAN: The lesion described lies in the lower third of the humerus (Fig 1) but does not extend down to the condyles. It seems to be a purely destructive process. There is no visible new-bone formation and no evidence of periosteal reaction. The roughening of the cortex is seen on either side of the shaft, much higher on the humerus. The spine, both femurs and the bones of the pelvis and lumbar spine show no definite disease. The lung fields are clear, the heart is not remarkable. I cannot make any statement about the abdominal viscera. The film is not of diagnostic quality.

DR FRANSEEN: Is the mottling in the center merely an area of irregular bone destruction, with no evidence of trabeculation?

DR WYMAN: I interpret the mottling as bone destruction, with residual areas of medullary trabeculation and some areas of residual cortex remaining between the areas of destruction. I think the process may have started centrally and extended to involve the entire thickness of the bone.

DR FRANSEEN: The x-ray appearance is different from what I had visualized from the written description. I did not appreciate that the periosteal reaction was so far away from the main lesion.

To continue the discussion, I can say that I am not familiar with any giant-cell tumor that has taken on an appearance such as this even when a pathologic fracture has occurred through it. If we, then, go on to consider other primary malignant tumors, Ewing tumor must be thought of. In this respect, again, the age of the patient is very important. I know of no case of Ewing tumor in this age group, but as in any bone lesions, it can perhaps occur. I met Dr Simmons just before this conference and asked him if he remembered any patient with Ewing tumor in this man's age group, but he could remember none. Geschickter and Copeland\* have reported no case in a patient so old as this man. We have all seen bizarre x-ray pictures in Ewing tumor, but there is no suggestion here of lamination of the periosteum or the other signs that are usually

associated with this tumor. As you perhaps know, at least 50 per cent occur in adolescence, with tapering off of the age incidence at either end. The tumor rarely occurs in the thirties. Age in itself is a strong argument against a Ewing tumor in this case, but, again, one cannot exclude it entirely.

Multiple myeloma should be considered, but this patient at forty-eight is not too good a candidate for it. This lesion is not the purely destructive lesion by x-ray study that one usually associates with multiple myeloma, and to have an isolated lesion in an extremity without evidence elsewhere would be extraordinary in multiple myeloma. In this disease the serum protein is sometimes elevated, but we do not have this determination to help us. The character of the patient's pain, which showed remissions between aggravations by trauma, is suggestive of multiple myeloma in a general way, but these are about the only facts I can find in its favor. There was no Bence-Jones protein in the urine and no evidence of nephritis on urinalysis, the latter frequently accompany the lesion. So much for multiple myeloma.

Considering other malignant bone tumors, malignant tumors of cartilaginous origin usually show some trabeculation, and this lesion, according to the x-ray interpretation, gave no suggestion of trabeculation, but rather irregular mottled areas of destruction. The osteolytic form of osteogenic sarcoma must more seriously be considered in a destructive lesion such as this appeared to be. There was not enough new-bone formation to consider the osteoblastic form of osteogenic sarcoma. The osteolytic form can begin subcortically and, as it gets larger, extend to a more central position, as in this case. Pathologic fracture, as in this case, is common. However, osteogenic sarcoma, as Dr Simmons has pointed out so frequently, is uncommon at this age unless associated with Paget's disease. However, there is some overlapping of age groups, and osteolytic sarcoma cannot be excluded on the basis of age alone. Reticulum-cell sarcoma must also be considered, and I would be unable definitely to exclude this lesion without a biopsy. I see no reason to consider other bone-destructive lesions such as eosinophilic granuloma. I have had no personal experience with them, but know that they usually occur in much younger age groups, particularly in children.

In the neoplastic group, we are then left to consider secondary or metastatic lesions of bone. A secondary lesion of Hodgkin's disease taking this form, without any other evidence of it elsewhere, would be very uncommon because bone involvement of this type would usually occur only in late stages of the disease. I think we can disregard the lymph nodes described in the groins, because, in my experience, nodes of this description can be felt in almost any person, so that I see no reason for considering Hodgkin's disease seriously.

\*Geschickter, C. F., and Copeland, M. M. *Tumors of Bone*. 709 pp. New York: American Journal of Cancer, 1931. P. 640.

I think, however, that metastatic carcinoma must be considered very seriously, since the picture is entirely consistent with that diagnosis. In a woman, the breast would, of course, be regarded as a primary source, but this man's breast was presumably easily examined, and a carcinoma would have been discovered if present. The most common sources to consider in this case are the prostate and kidneys. Metastases from prostatic carcinoma are apt to show more osteoblastic activity than this lesion did, but some that we have seen have been almost completely osteolytic. An isolated metastasis like this in an extremity is uncommon in carcinoma of the prostate. Renal-cell carcinoma frequently produces a soft, pulsating tumor. In this case there is no description of the consistence of the tumor. The few that I have seen have been confined especially to the sternum and upper end of the humerus. This site, in the lower end of the humerus, is more unusual. The metastases from renal-cell carcinoma are often a more expanding type of tumor than this — this tumor mass was only 2 5 by 5.0 cm. That is as far as I can go, since nothing is said in the record about examination of the prostate or kidneys.

I had the impression as I first read through the record that the most likely diagnosis would be an osteolytic form of osteogenic sarcoma. On looking at the x-ray films, however, a metastatic lesion seems more likely. In any lesion like this, we have been taught that the only approach is to consider it a malignant lesion of bone until proved otherwise, and that the only method by which an exact diagnosis can be made is by biopsy with preparation for amputation if the lesion proves to be malignant. If I have to make a definite diagnosis from the appearance of the x-ray film, I say that this was probably metastatic carcinoma, and that is as far as I am willing to go.

Sarcoma, (?) reticulum-cell type

#### DR. FRANSEEN'S DIAGNOSIS

Metastatic carcinoma

#### ANATOMICAL DIAGNOSIS

*Metastatic renal-cell carcinoma*

#### PATHOLOGICAL DISCUSSION

DR. EDWIN F. CAVE: I saw this man after he had been admitted to the Baker Memorial Hospital. He was wearing a splint on the right arm. He had a fracture through the diseased area of the lower end of the humerus, and a good deal of swelling of the distal end of the arm and elbow. We could not make an accurate diagnosis, so we did a biopsy, separating the muscles, which were edematous.

The radial nerve was retracted, and we came into the fracture line. The bone was spongy and rather necrotic, the medulla was easily entered, and we took specimens from the cortex, the medulla and the periosteum. An attempt was made to do frozen sections at the time, but nothing conclusive was determined from the sections, so we closed the wound and waited for a report.

DR. TRACY B. MALLORY: The tumor in this case was extensively necrotic, and not until the permanent sections were cut were we able to find areas suitable for diagnosis. When we finally got some viable tumor it was quite evident that we were dealing with carcinoma, with large, clear, vacuolated cells very strongly suggestive of renal origin. Will you go on from there, Dr. Cave?

DR. CAVE: We debated then whether we should study the patient further by doing an intravenous pyelogram. Dr. Grantley Taylor was asked to see him, and he agreed that amputation was indicated and we proceeded with that. Amputation was done about two weeks after the biopsy. We amputated through the surgical neck of the humerus. The wound healed primarily. After that Dr. Chute and Dr. Colby saw the patient, and renal studies were done.

DR. MALLORY: Dr. Wyman, will you show the pyelogram?

DR. WYMAN: The pyelogram shows a tumor in the upper portion of the kidney, displacing the calyces.

DR. RICHARD CHUTE: I was presented with this problem on account of the fact that a number of cases have been reported in which a solitary metastasis from a renal-cell carcinoma has been removed and later the original source found and removed, and the patient remained "cured" for a good number of years. It seemed to us reasonable to extirpate the focus, therefore, Dr. Soutter and I did a nephrectomy. Dr. Soutter might like to say something about the technic and the result.

DR. LAMAR SOUTTER: This is the third case of a transthoracic nephrectomy done in this hospital for carcinoma. The reason for using this approach is that it provides more room for radical surgery. The exposure is better to cut the renal vein on the right side of the spine and the renal artery at the aorta and to remove the regional lymph nodes and the adrenal gland. That was done in this case.

DR. MALLORY: The amputated arm showed a mass of necrotic tumor, again with recognizable areas of renal-cell adenocarcinoma, and the resected kidney showed characteristic hypernephroma. The tumor was extensive enough to have invaded the renal vein and extended along nearly two thirds of the way to the vena cava as they often do.

The patient is still convalescing on the wards and is doing well.

## FEDERAL SUPPORT FOR MEDICAL EDUCATION

"THE philosophies of one age have become the absurdities of the next, and the foolishness of yesterday has become the wisdom of tomorrow." Half a century ago Osler<sup>1</sup> thus indicated the fluctuations of thought with which men sometimes measure their problems and devise their solutions. The problems are always vivid and immediate, whereas their solutions seem limited — so limited that men find themselves able to move in only one direction or not at all. Wars become inevitable, and so do Government subsidies, but is this wisdom or is it foolishness? Medical education in the United States is today based upon the highest standards in the world and yet whenever it is surveyed it is easily shown to be inadequate and in immeasurable need

of improvement. In a less prodigal age we should have said that we were living far beyond our means, but none is living beyond his means today until he has completely exhausted all chance of Government support. The air is full of talk of such support for medical students, medical research, medical education and medical practice.

The American Academy of Pediatrics has recently released a recommendation for federal support of pediatric education.<sup>2</sup> The figures presented are said to reveal a startling lack of adequate training on the part of those who are caring for children. On the other hand if such figures were broken down into groups of those whose hospital training or lack thereof was received ten, twenty and thirty or more years ago, it might become apparent that we are on the very crest of a wave of improvement in pediatric training as judged by time spent in pediatric hospitals after graduation from medical school. Certainly there are more candidates than there are opportunities for approved residency training in pediatrics, and in all the other specialties as well. When one turns to the need for more physicians trained in the care of children in the remote and rural areas, fellowships are suggested for medical graduates "committed to return to practice in an area of need." Many have tried, but no good answer has yet been framed for the old question of how they are to be kept down on the farm. The cost of medical education to the student is also cited as a reason why there may be a tendency on the part of young doctors to renounce special training or to settle in the urban areas where professional life may be economically easier. The recommendations are specific that an appropriation of \$5,000,000 be authorized, to be administered by the Federal Security Administration in direct support of pediatric education. Half of this would go to the departments of pediatrics of the approved medical schools in accordance with need and student enrollment. One and a half million dollars is recommended for scholarships and fellowships or other purposes directly related to pediatric education, and \$1,000,000 is recommended for allocation to states in need because of their remote and rural areas into which physicians cannot now be induced to move.

Other specialties occupy educational grounds no less valid and deserving, what would be the tendency for them to generate equalizing pressures? Medical schools are constantly being surveyed by professional groups gathering data about this or that special interest. Such surveys are generally followed by reports indicating the existing inadequacies and suggesting minimum standards. It is as though our leaders were busying themselves by seeking to perfect each small part of a mosaic, but neglecting to concern themselves with the over-all picture or the condition likely to supervene ten years hence.

That the eyes of different groups are not focused upon the same objective is emphasized by recent divergent estimates concerning the likelihood of a shortage of physicians by 1960.<sup>3</sup> The United States Public Health Service and the Federal Security Administration anticipate a shortage of between 30,000 and 50,000 doctors in another decade, whereas the American Medical Association estimates that by 1960 there will be in this country at least 1 physician for every 700 people—a greater ratio than at present or in the immediate past. The number of physicians is increasing at a relatively more rapid rate than that of the population as a whole. This would be all right if there were to be more for them to do in the coming era than there has been in the past. If there are to be vast increases in hospital and research facilities more medical manpower will be needed. On the other hand, too many physicians, like too many cooks, could be a menace to the people's health, especially if it is necessary to sacrifice quality to produce the larger number, and if they must eke out a living by private practice in this apprehensive and neurotic world.

Whether an extension or permanent modification of the present GI bill of rights for all medical students would be helpful (and to whom) is another large subject. Such an extension would not produce more doctors. It might make medical education available to students who would otherwise seek a different training or vocation. It would surely attract the type of student whose hat is in the ring for a scholarship. Medicine has need for the best brains that can be recruited, it also needs character. Brains are more easily measured than character,

but character motivates and guides the application of brainpower, and is therefore recognized as a raw material without which a good doctor cannot be educated regardless of the resources at his disposal. If a formula could be devised that would recognize and attract character as readily as brains are now recognized, medical educators would find the task of selecting students greatly lightened and better performed than at present.

Expansion of federal largess is potentially without limit—but there is a fly in the lard. The members of the medical profession are not unanimously convinced that Government support can be contrived without Government interference. In a recent Washington Report<sup>4</sup> an aide of the Federal Security Administrator is quoted as asking the question

Why must Uncle Sam ever be suspected, when he lends a helping hand, of having something up his sleeve? Whoever can answer this question can also tell us whether all this is wisdom or foolishness.

#### THE WORLD MEDICAL ORGANIZATION

POSSIBLY unnoted by many, in the present confused and disturbed condition of the world, was the announcement from the recent Interim Session of the House of Delegates of the American Medical Association in Cleveland on the formation of a World Medical Organization.

This was agreed to in principle at the Atlantic City Annual Session in June, 1947, and authority for participation wholeheartedly voted by the House of Delegates. The organization meeting was held in Paris in September, with four members of the Board of Trustees as the American representatives. One hundred and twenty-five delegates from forty-eight nations attended. From the reports on the sessions, one gathers that some of the meetings resembled those held by the United Nations at Lake Success. Apparently, there were many trying moments when patience, tolerance, long suffering

and vision were required" — not to be wondered at when one considers the diversity of tongues, suspicions and fears. Apparently, Drs Henderson, Bauer, Irons and Sensenich did a splendid piece of medical statesmanship. The details of the organization need not be reviewed here but should be read in the January 17 issue of the *Journal of the American Medical Association*, where they are briefly set forth.

A few essentials may be stated. This newly formed organization constitutes a potentially important agency for peace as well as health. It is to be distinguished from the World Health Organization, which is part of the United Nations set-up. It is to the medical picture what the American Medical Association is to American medicine, and the World Health Organization of the United Nations in that picture is comparable to the United States Public Health Service. Under the present temporary organization, illustrative of its broad international scope, the president is from Paris, the president-elect from Czechoslovakia, the treasurer from Switzerland, and the ten elected members of the General Council from England, Sweden, France, Spain, Australia, India, China, Cuba, Canada and the United States. The permanent secretariat is to be in New York City at the Academy of Medicine.

This organization may well prove to be the first step toward a better understanding among nations, and, if so, it will be of inestimable value. As has been well said, "If the doctors in the world cannot get together, it is doubtful if anyone can."

## DISPLACED PERSONS

MEMBERS of the medical profession are commonly accused of taking less interest in world affairs than the average responsible man with the same degree of education. It would be truer to say that specialized training has taught physicians the value of accurate detailed facts and the practical difficulty of obtaining them. Factual information about the 850,000 homeless people in Europe has recently been issued in a twenty-six-page pamphlet by the Citizens Committee on Displaced Persons with a view to clarifying the world problem that their plight has created.

These European ex-slave laborers have put the United States in a very embarrassing position indeed. It is *our* opposition to their forcible repatriation to Soviet-dominated countries and *our* insistence on their right to a home in a free country that is keeping them in concentration camps three years after the date of "liberation." To be sure, we are paying the bills. The camps in Germany and Austria are likely to cost us a quarter of a billion dollars in 1948. Not only our national economy but also our international reputation for good faith is being damaged. Fifty-three times in three months has the Soviet propaganda office broadcast the story to the world of how our great humanitarian democracy is letting its former allies rot in camps for displaced persons. France, Belgium and the United Kingdom have already admitted 6000, 20,000 and 24,000 displaced persons, respectively, as immigrants and have agreed to admit 69,000, 66,000 and 80,000 more in the immediate future. Other democracies have made similar commitments. The United States has admitted 22,000 and is now debating whether to admit any more.

It is not necessary to be vague regarding the type of persons represented. They have recently been investigated in their camps by a special nonpartisan committee of the House Foreign Affairs Committee and are being surveyed by a similar committee of the Senate. They are Poles, Latvians, Lithuanians, Estonians, Yugoslavs, Greeks, Ukrainians, Czechs and Jews — all homeless and all certain of persecution or death in their former countries. Half are women and children, almost all are young, and many are skilled. For example there are 21,175 skilled construction workers, including architects, draftsmen, surveyors, electricians and carpenters, 38,654 persons trained in the professions (teachers, musicians, librarians, nurses, physicians, artists, lawyers, engineers and so forth), 95,427 agricultural workers and many other representatives of valuable skills and trades listed in the most recent census. Investigators report them to be good citizenship material.

An emergency bill is before Congress (Stratton Bill, HR 2910) to admit approximately half the displaced persons to the United States by increasing the annual immigration quota for a period of four years. First priority would be given to the relatives

of United States citizens and veterans. If all who could qualify under our basic immigration laws were admitted they would amount to only 0.3 per cent of the population, or less than half the quota of immigrants whose admission to this country was prevented during the four war years. Secretary of State Marshall strongly favors this action and says, "Now is the time to act. Robert P. Patterson states that, 'on the grounds of economy, humanity and the furtherance of the world peace,' Congress should enact HR 2910. The presidents of the AFL and CIO believe that such action will not have any adverse bearing on the American workman' and that 'the DP's would in fact stimulate employment.'" Earl G. Harrison, former commissioner of immigration and now dean of the University of Pennsylvania Law School and chairman of the Citizens Committee on Displaced Persons has made the following comment:

Our rate of population growth has been slowing up and our population has been growing older. Immigration gave us strength and nonishment when we were young in the family of nations. It can help us again. It can give us the strong, vigorous population needed to maintain our leadership among world powers.

Justice Owen J. Roberts adds:

If we are serious in our concern for personal freedom we must prove it by action. If we make the gesture for DP's other countries will follow our lead.

The humanitarian aspect of this situation is easy enough to comprehend. The political, economic, financial and international phases are being clarified by the information now becoming available. A great many people whose opinions deserve unqualified respect believe that the Stratton Bill should be passed, and passed at once. We have become accustomed to suspect a joker in most election-year legislation, but it is difficult to find a joker in this bill.

## THE FALLACY OF THE CRUDE DEATH RATE

In a statement released by the Federal Security Administrator, Oscar R. Ewing, the crude death rates for the various states were discussed. In 1945 the death rate for the country as a whole was 10.6, whereas in 1946 it was 10.0. The reported rate for

Massachusetts dropped from 12.2 to 11.2, although there was an actual increase of 265 deaths. The only explanation for a decreased death rate with a practically constant number of deaths would be an increase in the population. Demobilization of troops caused an increase, but the extent is problematical, and at the present time estimated populations must be used in the determination of rates. Considerable error may also be found in such estimations when shifts in population have affected a large proportion of the people, such as occurred among civilians during the war years. Until the next census is taken, rates can only be approximated, and little significance should be placed in a reported drop in the crude death rate from 12.2 to 11.2.

The variations in the rates in different parts of the country are influenced by age, sex and race differences. An older part of the country, such as New England, is expected to have a higher death rate than that of the more recently settled communities. If valid comparisons of mortality risk are to be made, adjustments are necessary to allow for differences in population structure. It is interesting to note that, despite the many changes in the trends of individual disease as well as population changes, the total number of deaths in Massachusetts has remained fairly stationary for the last quarter century, averaging about 50,000 deaths per year.

## MASSACHUSETTS MEDICAL SOCIETY DEATHS

**BARTON** — John A. Barton, M.D., of Fitchburg died recently. He was in his sixty-seventh year. Dr. Barton received his degree from Harvard Medical School in 1897. He was head of the Eye, Ear, Nose and Throat Department of the Burbank Hospital for thirty years, and was a member of the New England Otolgical and Laryngological Society.

His widow, a son and a granddaughter survive.

**ELLIS** — Arthur H. Ellis, M.D., of Greenfield, died on March 4. He was in his sixty-seventh year.

Dr. Ellis received his degree from Dartmouth Medical School in 1907. He was a former president of Franklin District Medical Society and was a member of the staffs of Franklin County Public Hospital, Greenfield, and Farnen Memorial Hospital, Montague City, and a fellow of the American Medical Association.

His widow, four daughters and six grandchildren survive.

**EVERETT** — Frederick L. Everett, M.D., of Springfield died on March 6. He was in his seventy-sixth year. Dr. Everett received his degree from Cornell University Medical College in 1902.

His widow, two daughters and nine grandchildren survive.

**FISH** — John E. Fish, M.D., of Canton, died on March 30. He was in his seventy-fifth year.

Dr. Fish received his degree from Dartmouth Medical School in 1896. He was a former president of Norfolk District Medical Society and was formerly superintendent of the Massachusetts Hospital School in Canton. He was a fellow of the American Medical Association.

His widow, two daughters and two sons survive.

**HOSLEY** — Walter A. Hosley, M.D., of Topsfield, died on March 25. He was in his seventieth year.

Dr. Hosley received his degree from Harvard Medical School in 1904.

Two daughters survive.

**HUNT** — Reid Hunt, M.D., of Boston, died on March 7. He was in his seventy-eighth year.

Dr. Hunt received his degree from College of Physicians and Surgeons of Baltimore in 1896. He was associate professor of pharmacology at Johns Hopkins University School of Medicine from 1898 to 1903, chief of the division of pharmacology, United States Public Health Service, from 1904 to 1913 and professor of pharmacology at Harvard Medical School from 1913 to 1936. He was professor of pharmacology, emeritus, Harvard Medical School, a former chairman of the Council on Pharmacy and Chemistry of the American Medical Association and a member of the Association of American Physicians.

His widow survives.

**IRWIN** — Vincent J. Irwin, M.D., of Springfield, died on February 26. He was in his sixty-first year.

Dr. Irwin received his degree from Yale University School of Medicine in 1909. He was a member of the American Academy of Ophthalmology and Oto-Laryngology and a fellow of the American Medical Association.

His widow survives.

**LELAND** — Leslie P. Leland, M.D., of Worcester, died on March 16. He was in his sixty-fourth year.

Dr. Leland received his degree from Boston University School of Medicine in 1909. He was a former secretary of the Worcester District Medical Society and was a member of the New England Obstetrical and Gynecological Society and a fellow of the American Medical Association.

His widow and two daughters survive.

**MAY** — James V. May, M.D., of Belmont, died on December 24, 1947. He was in his seventy-fifth year.

Dr. May received his degree from University of Pennsylvania School of Medicine in 1897. He was a former president of the New England Society of Psychiatry, Massachusetts Psychiatric Society and American Psychiatric Association, and was a fellow of the American Medical Association.

**O'BRIEN** — John C. O'Brien, M.D., of Greenfield, died on March 18. He was in his eighty-fifth year.

Dr. O'Brien received his degree from University of Vermont College of Medicine in 1887. He was formerly a trustee of the Northampton State Hospital, town physician and physician to the Greenfield House of Correction, and was a fellow of the American Medical Association.

A son and a daughter survive.

## MEDICOLEGAL ABSTRACT

**Relation of Patient and Physician — Confidential communications and their possible disclosure in hospital records.** According to the terms of his oath the physician is bound to treat the communications of his patient in confidence. Legally, however, no such privilege existed under the common law. In some states, however, statutes have protected confidences revealed to the physician

for the purpose of adequate diagnosis and treatment. In states where such confidences are protected by statute the question may arise to what extent, if any, the protection is removed if the information revealed to the physician in confidence is made a part of a hospital record. Such a question was recently considered by the Supreme Court of Ohio.

In a proceeding in which it was sought to show that a will was invalid on the ground that the testator lacked the necessary mental capacity, hospital records were offered, consisting of the entrance slip, the physician's direction for the medication to be administered and treatment to be given the patient by the nurses, record of analyses of the blood and the urine of the patient and the day-to-day chart made and kept by the nurses who had charge of the patient while he was at the hospital. These charts recorded the food and medicine given and the condition and behavior of the patient, the fact that he was irrational at times, that he left his bed at unreasonable hours, that on one occasion he used a wastepaper basket as a commode, and that on several occasions he became unruly. Part of the record included notations of increasing administrations of sedatives culminating on the date that the will was signed. These portions of the record were all admitted in evidence. A verdict was returned that the writing in question was not valid as the last will and testament of the deceased, and judgment was entered for the contestant. The contestees sought a reversal on the grounds that the hospital record contained matters communicated confidentially to the physician and nurses of the deceased and should not have been admitted in evidence.

Ohio has statutes establishing a patient-physician privilege and also providing for the admissibility of hospital records, but the statutes do not specify the relation between the two. The court discussed the question whether or not the communications should have been admitted even though it found that the contestees had waived their privilege by permitting the physician to testify completely and without objection to all details of his diagnosis and treatment. However, the court stated:

The courts in most states having Physician-Patient Privilege Statutes similar to section 11494, General Code, generally hold that communications between Physician and Patient, not in the presence of third persons, for the purpose of diagnosis and treatment of the patient, if carried into a private hospital record or chart, remain confidential, and that such part of the chart or record is inadmissible in evidence unless the privilege is waived.

In discussing generally the admissibility of hospital records the court said:

Such a hospital or physician's office record may properly include case history, diagnosis by one qualified to make it, condition and treatment of the patient covering such items as temperature, pulse, respiration, symptoms, food and medicine given, analysis, of the tissues or fluids of the body, and the behavior of and complaints made by the patient.

The court drew a line between direct communication and observed facts or information obtained without communication. The difficulties in determining admissibility according to such a line of demarcation are evident. Portions of the record that report diagnosis and directions for treatment do not fall into either of the categories described by the court. Is the diagnosis admissible? And of what use is it to bar the communications on which diagnosis is based when the diagnosis and medication and directions for treatment clearly indicate the substance of the barred communication? In this case, therefore, part of the records included notations of increasing administration of sedatives that would be confidential if related to the physician by the patient but perhaps avoids the privilege when entered on the hospital record as an observed fact.

If the entire hospital record is admissible in evidence the purpose of the statute and of the physician's oath would be nullified, and professional confidence would be limited to unrecorded information (*Wes v Wes*, 72 N E [2nd] 245, 1947).

## MISCELLANY

### AMERICAN COLLEGE OF SURGEONS APPROVES USE OF NURSE ANESTHETISTS

The Board of Regents of the American College of Surgeons at a meeting on February 22, adopted the following resolution:

The American College of Surgeons regards with deep concern the actions of some physician anesthesiologists in giving the impression to the laity in the public press that it is unsafe for experienced nurse anesthetists to conduct surgical anesthesia. While it supports the increasing tendency of having physician anesthesiologists in charge of surgical anesthesia, it deplores at this time any propaganda for the elimination of the trained nurse anesthetist. On the contrary, the American College of Surgeons is of the opinion that, in view of the inadequacy in number of the physician anesthesiologists and in view of the splendid record of achievement of the nurse anesthetist institutions engaged in the training of nurses for this purpose should be encouraged to continue their programs.

### NATIONAL CANCER INSTITUTE

More than \$1 355,818 in federal grants in-aid from Public Health Service funds for cancer research and control has been announced by the Federal Security Administration. It was made on the recommendation of the National Advisory Cancer Council of the National Cancer Institute. Another \$8 000 000 in construction grants for new laboratory and clinical facilities has been recommended by the Council.

## NOTE

Dr Arthur Marvel Lassek, head of the Department of Anatomy, Medical College of the State of South Carolina in Charleston since 1935 has been appointed Waterhouse Professor of Anatomy at Boston University School of Medicine, effective July 1. Dr Lassek will succeed Dr Jesse LeRoy Conel, a member of the medical faculty since 1923.

## CORRESPONDENCE

### RESTORATION OF LICENSE

To the Editor: At a meeting of the Board of Registration in Medicine held March 18 it was voted to restore the registration to practice medicine to Dr George J. Orlandi, 20 Charlotte Road Newton Centre (formerly of 1234 Blue Hill Avenue Dorchester).

H QUINBY GALLUPE, M.D. Secretary

State House  
Boston

## DEPRIVATION OF LICENSE

To the Editor: At a meeting of the Board of Registration in Medicine held March 18 it was voted to suspend the registration of Dr William P. Pratt 28 Adams Street, Quincy, for three months.

H QUINBY GALLUPE, M.D. Secretary

State House  
Boston

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*An Atlas of Anatomy*. By J. C. Boileau Grant, M.C., M.B. (Ch.B. F.R.C.S. (Edin.)) professor of anatomy in the University of Toronto. Second edition. 4 cloth 496 pp., with 991 illustrations. Baltimore: Williams and Wilkins Company, 1947. \$10.00.

This atlas was published first in 1943 and reprinted in 1944 and 1945. Dr Grant, in this edition has added more than two hundred illustrations including the wrist, superficial veins of the limbs, the inguinal region, abdominal viscera, suprathyroid region, mouth and the blood supply of the esophagus, stomach, duodenum, pancreas, bile passages, spleen and suprarenal glands. Also, the more common dissecting room variations, the epiphyses and schemes of the distribution of the cranial nerves and of the motor nerves to the extremities are considered. A good index concludes the volume. The book is well published in every way. The illustrations and color work are excellent. The atlas is recommended for all medical libraries.

*Overcoming Stammering*. By Charles Pellman. With a foreword by Frederick Martin, M.D., director of National Institute for Voice Disorders, Bristol, Rhode Island, and director of Speech Clinics, State Department of Education, Rhode Island. 8 cloth 160 pp. New York: The Beechurst Press, 1947. \$3.00.

Mr Pellman, an experienced practicing speech correctionist, analyzes and evaluates current methods of speech correction and treatment. He presents a plan for speech correction of stammering and stuttering based upon the physiology of speech and proper mental hygiene rather than on the functioning of the speech apparatus. His method may be used in the home by intelligent parents. The text ends with an autobiographic sketch of a stammerer by Aaron Pellman. A list of books and an index conclude the volume. The book is well published. It is recommended for medical and educational libraries.

*Procedure in Examination of the Lungs, with Especial Reference to the Diagnosis of Tuberculosis*. By Arthur F. Kraetzer, M.D., associate attending physician, Lenox Hill Hospital, physician to outpatients, New York Hospital and Instructor in medicine (dermatology), Cornell University Medical College. Third edition revised and with a preface by Jacob Segal, M.D. medical director, Los Angeles Sanatorium. Oxford Medical Publications. 8° cloth, 150 pp. with 16 illustrations and 14 plates. New York: Oxford University Press, 1947. \$3.50.

Dr Segal, in this revision of Kraetzer's manual has brought the subject up to date since the publication of the previous edition in 1935. The text of the second edition has not been disturbed, but the new material has been incorporated in an appendix of twenty-two pages and sixteen x-ray plates. An x-ray commentary on the correlation of signs leading to a diagnosis with histories of 13 cases and illustrated with the x-ray pictures, is included in the appendix. An index has been added for the first time. The volume is well printed with good type on good paper.

*The Dispensatory of the United States of America* By Arthur Osol, Ph G, M S, Ph D, professor of chemistry and director of the department of chemistry, Philadelphia College of Pharmacy and Science, and George E Farrar, Jr, M D, associate professor of medicine, School of Medicine, Temple University, and chief of Medical Service A, Episcopal Hospital 4<sup>th</sup>, cloth, 1928 pp Philadelphia J B Lippincott Company, 1947 \$16 50

This standard reference work has a remarkable record of one hundred and fifteen years of continuous publication. It was first issued in 1833 as *The Dispensatory of the United States of America*, by Drs George B Wood and Franklin Bache. In 1879, with the fourteenth edition, Dr H C Wood became associated with the elder Dr Wood, and in 1885, with the fifteenth edition, Dr H C Wood became the principal author. With the centennial edition Dr H C Wood, Jr, became the principal author, and he is now advisory editor to this twenty-fourth edition. The work was issued every few years from the beginning, and a number of editions were reprinted, except that editions were not published during the Civil War years, 1859-1864. The text is divided into five parts. Parts one and two, the major portion of the work, describe the drugs recognized by the *United States Pharmacopæia*, the *Pharmacopæia of Great Britain* or the *National Formulary* and the drugs not official in these works. The drugs are listed alphabetically in these two sections. The remaining parts list general tests, processes, reagents and solutions, veterinary uses and doses of drugs, and tables of the *United States Pharmacopæia* or the *National Formulary*. The tables on atomic and molecular weights, and on equivalents of weights and measures are especially valuable. A comprehensive index concludes the volume. The publishing is excellent in every way. Every effort has been made to reduce the weight and size of such a large volume. The text is printed in two columns on a good light paper with a good type. The price is very reasonable for the size of the book. The work is recommended for all libraries, medical and general, and to all persons interested in drugs.

*The Foot and Ankle Their injuries, diseases, deformities and disabilities* By Philip Lewin, M D, associate professor of bone and joint surgery, and acting head of department, Northwestern University School of Medicine, professor of orthopedic surgery, Post-Graduate Medical School of Cook County Hospital, attending orthopedic surgeon, Cook County Hospital, senior attending orthopedic surgeon, Michael Reese Hospital, and consulting orthopedic surgeon, Municipal Contagious Disease Hospital, Chicago. Third edition 8<sup>th</sup>, cloth, 847 pp, with 389 illustrations. With line drawings by Harold Laufman, M D. Philadelphia Lea and Febiger, 1947 \$11 00

This edition of a standard work has been extensively revised in the light of the vast amount of information gleaned from the records and experience of World War II. Much material has been added, and emphasis has been placed on compound fractures, crushing wounds and osteomyelitis. There is a special chapter on the military aspects of foot and ankle disorders. The sections on traumatic gangrene and amputations have been enlarged, and ringworm has been considered not only as a primary and sole infection but also as a complication of injuries. There is a special chapter on psychosomatic medicine as it relates to certain orthopedic conditions. The book is well published and is recommended for all medical libraries and to all persons interested in the subject.

*Diseases of the Nose, Throat and Ear* By William L Ballenger, M D, and Howard C Ballenger, M D, associate professor and acting chairman, Department of Otolaryngology, Northwestern University School of Medicine, Chicago, and surgeon, Department of Otolaryngology, Evanston Hospital, Evanston, Illinois. Assisted by John J Ballenger, M D, research fellow in otolaryngology, Northwestern University School of Medicine, Chicago. Ninth edition 8<sup>th</sup>, cloth, 993 pp, with 597 illustrations. Philadelphia Lea and Febiger, 1947 \$12 50

This edition of an authoritative textbook has been revised by the addition of much material. Obsolete material has been deleted, and portions of the text rewritten and amplified. There is a new chapter on "headaches and neuralgias of the face," and rhinoplastic reconstruction has been described. The special contributors have revised the chapters on arytenoidectomy for bilateral paralysis of the recurrent laryngeal nerves,

physiology and functional tests of the labyrinth and inflammatory diseases of the labyrinth and peroral endoscopy. The volume is well published in every way. The printing of a history of the editions on the back of the title page would be of value to reviewers and other interested persons. The book is recommended for all medical reference collections.

*Textbook of General Surgery* By Warren H Cole, M D, professor of surgery and head, Department of Surgery, University of Illinois College of Medicine, and director of surgical service, Illinois Research and Educational Hospitals, Chicago, and Robert Elman, M D, professor of clinical surgery, Washington University School of Medicine, assistant surgeon, Barnes Hospital, associate surgeon, St. Louis Children's Hospital, and director of surgical service, H G Phillips Hospital, St. Louis. Fifth edition 8<sup>th</sup>, cloth, 1160 pp, with 558 illustrations. New York D Appleton-Century Company, 1948 \$11 00

This standard textbook, first published in 1939 and last revised in 1944, in this new edition has been thoroughly revised to date. The type has been completely reset, and the volume repaged. The chapters on war and catastrophe surgery, surgical diseases of the chest and chemotherapy have been rewritten. The chapter on the nutritional requirements of surgical patients has been considerably expanded. A chapter has been added on surgical convalescence, including preoperative and postoperative care. The text is well written, and the material well organized. Selected references are appended to each chapter. Indexes of authors and subjects conclude the volume. The publishing is excellent except that the coated paper makes the volume heavy for its size. It is recommended for all medical libraries and all surgeons.

*A Text-Book of Bacteriology* By R W Fairbrother, M D, D Sc (Man), F R C P (Lond), director of the department of clinical pathology, Manchester Royal Infirmary, and special lecturer in bacteriology, University of Manchester. Fifth edition 8<sup>th</sup>, cloth, 480 pp, with 34 tables and 6 plates. New York Grunc and Stratton, 1948 \$6 50

This textbook, first published in 1937, and last revised in 1946, has gone through twelve printings of the five editions, a fact that attests its soundness as a textbook for students. The author has made a thorough revision of the text for this fifth edition. The book is an outline of the medical aspects of bacteriology. The material is divided into three parts: general bacteriology, systematic bacteriology and general technique. A good index concludes the volume, which is well printed with a good type by the lithographic process on light paper.

*Blood Pressure and Its Disorders, including Angina Pectoris* By John Plesch, M D, Budapest, M D, Germany, L R C P and S Edin and Glas. Second edition revised and enlarged 8<sup>th</sup>, cloth, 307 pp, with 125 illustrations. Baltimore Williams and Wilkins Company, 1947 \$6 00

Dr Plesch has revised this second edition of his monograph, first published in 1944, by the addition of material, chapters and case histories. Selected references have been appended to each chapter. The text represents the author's personal experience and research, and is not intended as a comprehensive treatise on the subject. The printing was done in Great Britain and is excellent. The type and paper are good. The book should prove useful to physicians interested in the subject.

*Biochemistry for Medical Students* By William V Thorpe, M A (Cantab), Ph D (Lond), reader in chemical physiology, University of Birmingham. Fourth edition 8<sup>th</sup>, cloth, 496 pp, with 36 illustrations. Baltimore Williams and Wilkins Company, 1947 \$5 00

This English textbook, first published in 1938, and last revised in 1943, has been revised to date. A chapter on the use of isotopes in biochemical investigations has been added, and the sections on protein structure, coenzymes, flavo-proteins, bile pigments and nutrition in wartime have been largely rewritten. The text is well written, and the material well organized. The type, printing and paper are excellent. The book should prove useful as an excellent summary of the subject.

*Malaria, with Special Reference to the African Forms* By W. K. Blackie M.D., Ph.D. F.R.C.P. (Edin.), D.T.M. & H. 8<sup>th</sup> cloth 104 pp., with a color plate Cape Town The African Bookman for the Post-Graduate Press 1947 10sh., 6d

This concise monograph presents the latest methods of treatment with quinine and the newest plasmodicidal drugs including mepacrine (atabrine), pamaquin and paludrine. The first chapter comprises a short historical review followed by chapters on the parasitology, pathology, clinical features, diagnosis, prognosis, treatment and prophylaxis of the various types of the disease. The material is well organized and well published in every way. The color plate depicting the various plasmodiae is excellent. A good index concludes the text. The monograph was published by the Bayer Pharma. publication fund of the Cape Town Post-Graduate Medical Association. The work is recommended for all medical libraries.

*Nursing in Modern Society* By Mary Ella Chayer, R.N. M.A. associate professor of nursing education Teachers College Columbia University 8<sup>th</sup> cloth 288 pp New York G. P. Putnam's Sons 1947 34.00.

This book has been written primarily for nurses, teachers and supervisors. The various current problems of nursing are discussed by the author in the following divisions: the impact of social forces upon nursing, the influence of social forces upon community health needs and building a better future for the nursing profession. Miss Chayer has called attention to the changing needs of society and to the changes that have already taken place in the nursing profession. The last chapter summarizes the twelve cardinal principles of professional service. The text is well written in an easy style, and the material is well organized. The type paper and printing are excellent. A list of references and one of questions for study are appended to each chapter. A comprehensive general bibliography and a good index conclude the volume. The work should prove useful as a reference work in schools of nursing and as a textbook for postgraduate students. It is recommended for the reference collections of all medical libraries.

*Benjamin Silliman 1779-1864 Pathfinder in American Science* By John F. Fulton, M.D. and Elizabeth H. Thomson 8<sup>th</sup> cloth, 294 pp. with seventeen illustrations New York Henry Schuman 1947 \$4.00

Benjamin Silliman is of interest to the medical historian because of the responsible part he took in organizing Yale University School of Medicine in 1813. He was eminent as a chemist and geologist and as a teacher of science. He established the great Peabody Museum of natural history and founded the first gallery of fine arts in an American academic institution, the Trumbull Gallery of Yale College. He was also largely instrumental in founding the Sheffield Scientific School, first called the School of Applied Chemistry. The authors of this well written biography for the general reader cover the professional life of Silliman from the time he was appointed professor of chemistry at Yale in 1802 until his retirement in 1853. The story is told in an easy narrative style. The book is well published and should be in all medical and scientific historical collections. It is one of a series in *The Life of Science Library*.

*400 Years of a Doctor's Life* Collected and arranged by George Rosen M.D., and Beate Caspar-Rosen, M.D. 8<sup>th</sup> cloth 429 pp New York Henry Schuman 1947 \$5.00.

This interesting anthology is made up of excerpts taken from formal autobiographies, letters and other writings of physicians, dead and living of the past four hundred years. The material is arranged according to epochs and incidents in a doctor's life: early years, school days, medical student days, the practice of medicine, scientist, scholar and teacher, the doctor marries, the doctor as a patient, the doctor goes to war, writing and politics; and reflections on life and death. The selections are preceded by short biographic notes or comments. The absence of direct references to the sources of the selections will be decry by the historian and bibliographer. A number of physicians appear more than once in different sections of the text and there should have

been an index to names to make the book useful as a reference work. The type, printing and paper are excellent. This unusual historical book should be in all collections of medical and general history.

*Calcium and Phosphorus in Foods and Nutrition* By Henry C. Sherman Ph.D. Mitchell Professor of Chemistry emeritus Columbia University 8<sup>th</sup> cloth 176 pp with seven figures and twelve tables New York Columbia University Press 1947 \$2.75

This semipopular monograph presents in plain language a summary of the place of calcium and phosphorus in present-day nutrition. The first chapter discusses the role of calcium and phosphorus in nature, in agriculture and in human nutrition. The following chapters deal with calcium in the body, the effects of food and growth upon the calcium content, chemical forms and nutritional functions of phosphorus, calcium and phosphorus requirements and the problem of necessary and optimal intakes and foods as a factor in the nutritional provision of calcium and phosphorus. An extensive bibliography of forty-four pages is appended to the text. A good index concludes the volume. The text is well written in a pleasing style and the material is well organized. The publishing is excellent. The printing is well done with a good type on a good light paper. The volume is recommended for all medical and general libraries and to all persons interested in the subject.

*Surgical Disorders of the Chest: Diagnosis and treatment* By J. K. Donaldson M.D. associate professor of surgery and in charge of thoracic surgery University of Arkansas School of Medicine, and member of surgical staff, St. Vincent's Infirmary and visiting staff, Baptist Hospital, Little Rock, Arkansas. Second edition thoroughly revised 8<sup>th</sup> cloth 485 pp with 146 illustrations and 2 color plates Philadelphia Lea and Febiger 1947 \$8.50.

This new edition of a standard treatise has been revised to include the knowledge gained during World War II. Decortication of the lung is discussed in some detail. Selected references are appended to each chapter and a good index concludes the volume. The publishing is excellent in every way. The book is recommended for all medical libraries and to surgeons interested in the subject.

*Principles of Occupational Therapy* Edited by Helen S. Willard A.B. O.T.R. director Philadelphia School of Occupational Therapy and Clare S. Spackman, S.M. in Ed. O.T.R. director, curative workshop Philadelphia School of Occupational Therapy director Occupational Therapy Department Hospital of the Graduate School of Medicine University of Pennsylvania and assistant director, Philadelphia School of Occupational Therapy 8<sup>th</sup> cloth 416 pp with 46 illustrations Philadelphia J. B. Lippincott Company 1947 \$4.50.

This new textbook is the joint work of twenty specialists in the field of occupational therapy. The text is divided into two sections, basic concepts and applied principles. The first section deals with the history, development, scope, educational aims and activities of the subject and factors in the organization of occupational therapy departments. The second section discusses the place of the therapy in general and special hospitals with a chapter on children's hospitals and pediatric services and in United States Army and Navy hospitals during World War II. In this section there are chapters on the use of occupational therapy for patients with mental disease and tuberculosis, the visually handicapped and for patients with physical injuries. The last chapter of over a hundred pages is subdivided into three sections dealing with treatment for limitation of motion of joints, flaccid paralysis and Industrial Injuries, for patients afflicted with cerebral palsy and for arthritic patients. The treatment is given in detail. The concluding chapter describes the rehabilitation program of the Veterans Administration. The work constitutes a treatise on the philosophy and practice of the subject. The text is well written, and the organization of the material is good. The volume is well published. The type is good and legible, and the printing on a soft, light paper pleasing to the eye is excellent. The book should be in all medical libraries and should prove valuable to all persons interested in physical therapy.

*A Text-Book of Mental Deficiency (Amentia)* By A F Tredgold, M D, F R C P, F R S (Ed), consulting physician to University College Hospital, London Seventh edition 8°, cloth, 534 pp., with 47 plates and 9 tables Baltimore Williams and Wilkins Company, 1947 \$8 50

This new edition of a standard textbook, last revised in 1937, has been brought up to date by the addition of considerable material. Some chapters have been rewritten, and the changes made by the British Education Act of 1944 relating to educationally subnormal and defective children have been incorporated in the chapter on English law concerning mental defectives. A good index concludes the volume. The text, printed in Great Britain, is well done with a good type on good paper. The book is recommended for all medical libraries and to all persons interested in the subject.

## NOTICES

### ANNOUNCEMENT

Dr Franklin G Balch, Jr, announces the removal of his office to 1180 Beacon Street, Brookline, for the practice of general surgery.

### SUFFOLK DISTRICT MEDICAL SOCIETY

The Suffolk District Medical Society will meet in Sprague Hall, Boston Medical Library, 8 Fenway, Boston, on Tuesday, May 4. The councilors will meet at 3 30 p m, and the annual meeting will be held at 5 00 p m.

### MASSACHUSETTS SOCIETY FOR SOCIAL HYGIENE

The annual meeting of the Massachusetts Society for Social Hygiene will be held at a dinner at the Boston City Club, 14 Somerset Street, Boston, on Wednesday, April 28, 6 00 p m. *Guest speaker* Dr Raymond A Vonderlehr of Atlanta, Georgia, medical director, Communicable Disease Center, United States Public Health Service, will speak on the subject "Past, Present and Future Responsibilities of the Social Hygiene Societies in the Control of the Venereal Diseases." Dr William A Hinton, chief of the Wassermann Laboratory, State Department of Public Health, and chief of the Laboratory Division of the Boston Dispensary, will be another guest of honor at the dinner. Dr George Gilbert Smith will preside.

The public is cordially invited to attend. For details regarding the program, reservations for the dinner and so forth, application should be made in writing or by telephone to the office of the Massachusetts Society for Social Hygiene, 1145 Little Building, Hancock 6-3176.

### NEW ENGLAND HEART ASSOCIATION

A meeting of the New England Heart Association will be held in the auditorium, Boston University School of Medicine, 80 East Concord Street, Boston, on Monday, April 26, at 8 15 p m. Dr James M Faulkner will preside.

#### PROGRAM

Diphtheritic Myocarditis Drs Norman H Boyer and Louis Weinstein

Clinical and Laboratory Features of First Attacks of Rheumatic Fever Occurring in Scarlet-Fever Patients Treated with Penicillin Drs Louis Weinstein, Louis Bachrach and Norman H Boyer

Acceleration of Flow in the Veins of Human Limbs by the Local Application of Pressure Drs Joseph R Stanton, Edward D Freis and Robert W Wilkins

Some Observations Concerning the Effect of Sympathectomy on the Human Heart Rate Drs Reginald H Smithwick, Earle M Chapman, Dera Kinsey and George P Whitelaw

The Effects of Veratrum Viride in Hypertensive Man Drs Edward D Freis, Joseph R Stanton, James W Culbertson, Julius Litter and Meyer H Halperin

Interested physicians and medical students are cordially invited to attend.

### NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

The regular meeting of the New England Society of Physical Medicine will be held at the Ring Sanatorium and Hospital, Arlington, Massachusetts, on Wednesday, April 21, at 8 p m. Dr Volta R Hall will speak on the topic "Physical Medicine in the Treatment of Psychiatric Conditions."

Members of the medical profession are cordially invited.

### AMERICAN CLINICAL AND CLIMATOLOGICAL ASSOCIATION

The annual meeting of the American Clinical and Climatological Association will be held at White Sulphur Springs, West Virginia, from November 1 to 3 (secretary, James Bordley, III, M D, Mary Imogene Bassett Hospital, Cooperstown, New York).

### AMERICAN CONGRESS OF PHYSICAL MEDICINE

The twenty-sixth annual scientific and clinical session of the American Congress of Physical Medicine will be held from September 7 to 11, inclusive, at the Hotel Statler, Washington, D C. Scientific and clinical sessions open to members of the medical profession in good standing with the American Medical Association will be given.

Full information may be obtained by application to the American Congress of Physical Medicine, 30 North Michigan Avenue, Chicago 2, Illinois.

### AMERICAN NEUROLOGICAL ASSOCIATION

The annual meeting of the American Neurological Association will be held in Atlantic City, New Jersey, from June 14 to 16, with headquarters at the Claridge Hotel (secretary-treasurer, H Houston Merritt, M D, Montefiore Hospital, Gun Hill Road, New York 67, New York).

### AMERICAN SOCIETY OF ANESTHESIOLOGISTS INC

A joint meeting of the American Society of Anesthesiologists, Inc, and the Western Divisions of the Canadian Anaesthetists' Society will be held at the Hotel Saskatchewan, Regina, Saskatchewan, Canada, on April 23 and 24. Physicians and medical students are invited.

### MAINE MEDICAL ASSOCIATION

The annual meeting of the Maine Medical Association will be held in Poland Spring from June 20 to 22 (secretary, Frederick R Carter, M D, 142 High Street, Portland 3, Maine).

### MINNESOTA STATE MEDICAL ASSOCIATION

The annual meeting of the Minnesota State Medical Association will be held in Minneapolis from June 7 to 9 (secretary, B B Souster, M D, Lowry Medical Arts Building, St Paul 2, Minnesota).

### MONTANA STATE MEDICAL ASSOCIATION

The annual meeting of the Montana State Medical Association will be held in Billings on June 18 and 19 (secretary, H T Caraway, M D, 115 North 28th Street, Billings, Montana).

### NEW MEXICO MEDICAL SOCIETY

The annual meeting of the New Mexico Medical Society will be held in Las Vegas from June 3 to 5 (secretary, H L January, M D, 221 West Central Avenue, Albuquerque, New Mexico).

(Notices concluded on page viii)

## CARCINOMA OF THE STOMACH\*

CLAUDE E. WELCH, M.D.,† AND ARTHUR W. ALLEN, M.D.‡

BOSTON

**S**URGICAL experience with carcinoma of the stomach at the Massachusetts General Hospital has been reviewed by Parsons<sup>1</sup> in previous papers covering the years 1922 to 1926, and the period from 1927 to 1936 by Parsons and Welch.<sup>2</sup> This report includes all patients admitted to this hospital on whom the diagnosis was made during the ten-year period 1937 to 1946 inclusive.

In the compilation of these figures, it is, of course, our hope to show that increased knowledge of the disease and its amenability to surgical attack have resulted in a steadily increasing five-year salvage rate. But it is of equal importance to consider the trends in management of patients with cancer of the stomach. In this brief summary, only our own experience can be considered, and no attempt is made to cover the voluminous literature comprehensively.

Several methods can be listed by means of which the curability rate can be increased. They are as follows: earlier diagnosis, that more patients with carcinoma will arrive in the hospital in a curable stage, more radical approach to the problem of gastric ulcer, that a certain number of cancers masquerading as ulcers will not be overlooked, extension of the type of operation so that by a wider excision of involved tissue, more cures may be obtained, and a reduction in the postoperative mortality, so that cases favorable for cure are not lost.

### DELAY BEFORE TREATMENT

Theoretically, if all patients were subjected to resection as soon as carcinoma of the stomach developed, all would be cured. Early diagnosis is therefore of the utmost importance. A vivid illustration of this point is furnished by the following case.

F. C. (M.G.H. 61931), a 58-year-old man entered the hospital on June 27, 1934, because he had vomited blood three times in the previous month. X-ray studies including

an upper gastrointestinal series, were negative. Gastroscopy showed chronic gastritis. Because of the possibility of carcinoma of the stomach, exploratory operation was performed. A 2-cm lymph node, found on the greater curvature, on frozen section showed 'highly malignant carcinoma. Because metastasis was already present, the surgeon did only a local excision of a small carcinoma of the greater curvature and did not remove any other lymph nodes. The pathological report was adenocarcinoma. The patient was living and well 12 years later. Despite the high malignancy of the tumor and an inadequate operation, early surgery effected a cure.

Cancer of the stomach, once established, is usually a very rapidly growing tumor. This is shown by the rarity of cancers of the stomach discovered incidentally at post-mortem examination, when death is due to some other cause. This behavior is in contrast to that of carcinoma of the prostate, which is not uncommonly discovered in autopsy specimens as an incidental finding.

This behavior of carcinoma of the stomach has been recognized for many decades, and a vast amount of educational information has been spread by various cancer-control groups in an effort to bring the patient with gastric symptoms to the surgeon in time for cure. At the same time, the medical profession has become more alert to the problem, and early diagnosis has been facilitated by better x-ray films and an increased use of the gastroscope.

It seemed probable, therefore, that a comparison of the delay before treatment would show a significant decrease in this last decade. To obtain comparable series, the length of time that elapsed from the onset of gastric symptoms to the date that the patient entered the hospital for treatment was determined for all patients undergoing operation during the twenty-year period 1927 to 1946. The delay in the first ten-year period was then contrasted with that in the latter (Fig. 1). The remarkable and unhappy result is that the two curves can be almost exactly superimposed.

Why does the average delay before treatment still remain at the high level of five months? Is it apathy on the part of the patient or neglect by the physician? One is inclined to believe that all

educational efforts have been negated by the radio and advertising columns with their promises of "relief for acid indigestion." Perhaps the medical profession should be satisfied that it is not fighting a losing battle against this propaganda, and conclude that if the public wishes to be cured of cancer of the stomach, it had better do something to aid itself.

No special attempt has been made in this study to discover the length of life of the untreated cases. It has been shown by Nathanson and Welch<sup>3</sup> and by Livingston and Pack<sup>4</sup> that the average duration

of life is about a year from onset of symptoms, and that 90 per cent of all patients are dead at the end of two years. The average delay from onset of symptoms to hospital entry of patients not subjected to surgery in the present series was about six months, at that time, operation was judged unwise or was refused by the patient.

Once the patient has been admitted to the hospital, he is studied completely. Endoscopy, as Benedict<sup>5</sup> has shown, is of great value, especially with lesions high in the stomach, since esophageal involvement may be observed. Peritoneoscopy is often valuable, especially if the patient has no symptoms of obstruction. If hepatic or peritoneal metastases are found, in the absence of obstruction, an operative procedure is contraindicated. On the other hand, if obstruction is present, the exploration is nearly always recommended, even if metastases are present, in the hope that a short-circuit may make the patient's life more comfortable.

TABLE 1 Types of Therapy Employed in All Cases of Carcinoma of the Stomach

PERIOD	TOTAL NO OF CASES	NO OF OPERATION	LAPAROTOMY ONLY	PALLIATIVE OPERATION	RESECTION
1927-1931	296	115	55	58	68
1932-1936	395	135	88	69	103
1937-1941	375	95	73	36	171
1942-1946	457	105	85	22	245

FIGURE 1 Delay in Seeking Treatment among All Cases of Cancer of the Stomach in Which Operation Was Performed. The duration of symptoms before hospital admission is divided into ten-year periods.

The therapeutic procedures employed in the various periods are listed in Table 1.

THE PROBLEM OF GASTRIC ULCER

The well known fact that gastric cancer frequently simulates benign gastric ulcer needs re-emphasis.

able, if healing is complete, repeat observation should be made one month after discharge from the hospital.

Another method of determining the diagnosis is by means of the cytologic smear, according to Papanicolaou's<sup>7</sup> technic. Fresh gastric washings are precipitated and stained. If malignant cells are found, the diagnosis is almost surely carcinoma. On the other hand, with known cancer of the stomach, the smear will be positive in only about two thirds of the cases. Thus, in the Vincent Memorial laboratory, the results to date have been as follows: in 50 cases of gastric ulcer or cancer in which gastric smears were employed, 24 patients proved to have carcinoma of the stomach, and the smears were positive in 15, of 26 patients without cancer, the smear was reported positive in 1, who proved to have a benign ulcer.<sup>8</sup>

If these recommendations are followed, there will be no significant delay in the recognition of gastric cancers. Furthermore, the very rare case of cancer that will "heal" under the best medical therapy (we have had at least 2 cases in this hospital) will soon be discovered, for the ulceration will recur after the patient leaves the hospital.

That the differential diagnosis of ulcer and cancer is still difficult is attested by the fact that 11 per cent of all the resections in the patients in the present study were made with the preoperative diagnosis of benign gastric ulcer. Fortunately, the delay before operation has been diminished in this group, because it has become appreciated that gastric resection for gastric ulcer produces excellent results, as shown by St. John et al.<sup>9</sup> and Judd and Priestley.<sup>10</sup>

One may ask how many lives might be saved if all the gastric carcinomas in this group were recognized and surgery performed at an early date. Since about 25 patients with apparent gastric ulcer appear in a year in this hospital, of whom about 14 per cent have carcinomas, 3 or 4 patients will be subjected to an earlier resection. Since the five-year curability rate is at least 40 per cent in this group, at least one additional cure a year should be expected in this hospital by early resection. But it is imperative for the surgeon to realize that, even when he has the stomach in his hands, he cannot make the differential diagnosis between ulcer and cancer, and that he must carry out the proper operation for gastric cancer.

#### EXTENSION OF THE OPERATIVE PROCEDURE

Gastric resection for carcinoma originally involved no attempt to excise any tissue but that of the stomach itself. However, the importance of removal of the regional lymph nodes along the lesser and greater curvatures was soon recognized, since the earliest metastases are usually found there. A second feature was emphasized by Castleman,<sup>11</sup> who showed the frequency of invasion of the proximal centimeter of duodenum by cancer of the stomach; he found that extension rarely proceeded beyond this level. A third site of early extension pointed out by Ogilvie<sup>12</sup> and Allen<sup>13</sup> is the great omentum. Metastases there are not uncommon, and may be overlooked except on microscopical section.

These three areas — the regional lymph nodes, the proximal centimeter of duodenum and the great omentum — should be removed with every resection for cancer of the stomach in which cure is the objective. Of course, if disease is to be left behind in other spots inaccessible to surgical removal, and only a palliative resection is planned, there is no need to remove the omentum in every case, although it is usually better to do so. After a long experience with this procedure, we are convinced that it carries no hazard and may contribute to a smoother convalescence.

As a corollary to the concept that gastric ulcer should be considered to be cancer until the pathologist proves it to be benign, it follows that the same operation should be carried out for gastric ulcer as for gastric cancer — that is, the removal of regional lymph nodes, great omentum and proximal duodenum. There is nothing more distressing to the surgeon than to read the pathologist's report

"carcinoma of the stomach, no lymph nodes are included with the specimen." Yet this happens all too frequently, and many patients who should have the best chances of cure are doomed because of an inadequate operation.

Proximal extension of carcinoma of the stomach to the cardia often requires the procedure of total gastrectomy. This operation, although mentioned in the previous report, was a surgical rarity at that time. The technic as subsequently developed and described by Allen<sup>13</sup> has been followed in this hospital. Since the patients subjected to the procedure usually have extensive tumors, the mortality rate is bound to be high, and the number of cures small. The postoperative life span, however, is often surprisingly long.

The operation of total gastrectomy, in addition to an increased postoperative mortality, has other undesirable features. After operation, it is difficult for many patients to maintain adequate nutrition, and an anemia of significant grade is not uncommon. Studies of patients who have had recurrence after subtotal resections for cancer usually show that metastatic involvement of lymph nodes is present but that the remaining stomach is uninvolved. For these reasons, we do not subscribe to Longmire's<sup>14</sup> theory that all patients with carcinoma of the stomach should be treated by total gastrectomy.

The operative attack on carcinoma of the stomach, has, in the past, been limited by inaccessible proximal extension of the growth into the esophagus and mediastinum. Although it was frequently possible to draw down 3 to 5 cm. of the esophagus and do a total abdominal gastrectomy, in many cases it was impossible to get an adequate margin above the tumor. Recently, Churchill<sup>15</sup> and Sweet,<sup>16</sup> in pioneer work in this hospital, have developed the technic of transthoracic gastrectomy. With this approach through the diaphragm, extension of the cancer into the esophagus is easily amenable to resection.

There are several organs that can be sacrificed, resection en bloc with the carcinoma of the stomach being used. Thus, the transverse colon, the pancreas, the spleen and rarely a local extension into the liver can be resected with the tumor. It is our experience that none of these patients will survive five years, but recurrence of the disease will be delayed.

There are, unfortunately, many areas of metastasis that cannot be removed surgically. Metastatic lymph nodes in the head of the pancreas about the superior mesenteric artery or about the hepatic artery are nearly always nonresectable. Whereas a regional lymph-node dissection of the left gastric artery may be done, a cure is not to be expected if the nodes about the celiac axis are involved. Metastatic lesions in the liver, if demonstrable, are indicative of widespread involvement of the organ. Removal of visible hepatic metastases will not

tribute to the postoperative comfort of the patient or increase the five-year survival rate. Peritoneal metastases are likewise indicative of widespread lymphatic involvement, local removal is useless.

The question might be asked regarding the relative importance of these extensions of the operative procedure so far as the control of cancer of the stomach is concerned. Five-year survivals are not to be expected if other viscera are involved as well as the stomach, so that massive resections of multiple viscera should be considered of value only as palliative procedures. On the other hand, there are rare

continued parenterally several days afterward. Sodium sulfadiazine was employed intravenously for some time before penicillin was available, and is still utilized in some cases. The sulfonamides cannot be used locally with safety, and, as a rule, they may be employed for only a short time because of the danger of renal complications.

Blood replacement has also played an important role. It is essential to remember that a normal red-cell count and hematocrit may be misleading in any given patient, since the blood volume may be low, as Lyons<sup>18</sup> has pointed out. Blood is now given

TABLE 2 Mortality with Various Types of Gastric Resection

TYPE OF OPERATION	NO. OF CASES		OPERATIVE DEATHS		OPERATIVE MORTALITY	
	1937-1941	1942-1946	1937-1941	1942-1946	1937-1941 %	1942-1946 %
Abdominal approach						
Subtotal palliative resection	35	32	13	2	37	6

Total resection	1	32	1	9	100	28
Totals	171	245	44	27		
Averages					26	11

five-year survivals after total gastrectomy. Obviously, the transthoracic approach has opened a new field that cannot yet be appraised accurately.

REDUCTION OF POSTOPERATIVE MORTALITY

The method of increasing the number of five-year cures of cancer of the stomach that has heretofore seemed to offer the most promise has been the reduction of excessive postoperative mortality. Thus, in the period 1932 to 1936, the mortality of gastric resection for cancer was 25 per cent. If these patients had not died, the five-year cures following resection would have increased by the same percentage.

It is gratifying to note that the mortality of resections has declined appreciably in recent years. The factors that have contributed are chiefly improved anesthesia, more careful blood, protein and vitamin replacement and chemotherapy. The anesthetic agent now employed is most commonly ether, by intratracheal administration, although our choice in patients who are not to have the diaphragm opened is continuous novocain administered in the spinal area by the method of Arrowood and Foldes.<sup>17</sup>

Local and parenteral use of penicillin just before, during and after operation has contributed a great deal to a smooth convalescence. Especially in transthoracic approaches, Sweet<sup>18</sup> has found that the use of penicillin has practically eliminated the complication of empyema. It appears to be no less effective in the peritoneal cavity. For full effect, it should be started before operation and

very liberally, therefore, despite normal laboratory figures. Likewise, intravenous amigen or amino acids and vitamins are administered in large doses when indicated preoperatively and as a routine measure postoperatively.

A technical contribution of great importance is that of Allen and Donaldson,<sup>19</sup> who introduced the routine use of double jejunostomy after gastric resections. The proximal tube is led back through the gastroenterostomy, and the distal one serves as a jejunostomy for feeding. Thus, the stomach is decompressed postoperatively without the use of a Levine tube. Stomal obstruction, which occurred in about 1 out of 20 patients in the series of Allen and Welch,<sup>20</sup> is no longer to be feared as a complication.

Although pulmonary emboli have not been eliminated as a cause of death, they have been reduced in number in recent years by prophylactic ligation of the superficial femoral veins, by the method of Allen, Linton and Donaldson.<sup>21</sup> We believe that this procedure is indicated in any patient who has a curable lesion, preferably at the time of resection, or within forty-eight hours thereafter.

These advances in therapy have resulted in a definite decrease in the number of postoperative deaths. Table 2 and Figure 2 show that the percentage of postoperative deaths has consistently diminished although the operability has increased.

To determine the effect of postoperative mortality on the curability rate, it is necessary to divide the resections into various groups (Table 2). Subtotal resections "for cure" represent cases in which the

surgeon has removed all gross cancer from the abdomen, and is the group that actually contains nearly all the cured patients "Palliative" subtotal resections include cases in which cancer is left behind in inaccessible areas at the time of resection, no cures are to be expected. With total gastrectomies five-year cures are very rare, whereas trans-thoracic gastrectomies have not been done long enough to evaluate the curability rate. Hence, only subtotal resections for cure need be considered

FIGURE 2. Prognosis in Cancer of the Stomach. The fate of all patients entering the hospital with this diagnosis is demonstrated by decades.

The postoperative mortality in this group was 11 per cent in 1937 to 1941 and 3 per cent from 1942 to 1946. This means that the factor of postoperative mortality can, at present, no longer be reduced significantly, and that other methods must be found to increase the number of cures.

#### FIVE-YEAR SURVIVALS

What, then, is the ultimate fate of the patient who enters the hospital with carcinoma of the stomach? A graphic summary, comparing the results of the present decade with those of the last, is given in Figure 2, in which the results from 1927 to 1936 are shown by the circled figures. The results in the present series are included in the heavy squares. Incidentally, it may be noted that, in the last five-year series in which it was possible to determine end-result so far as five-year cures are concerned (1937 to 1941), only 4 patients have been untraced. They are considered in the tables to be dead of disease. Several trends are immediately discernible: the number of apparently operable patients has risen from 65 per cent to a level of 75 per cent, the patients who have an operation are much more likely to have a gastrectomy than they were before (50 per cent of all cases, compared with 25 per cent), whereas the percentages of exploratory laparotomies remain about the same and those of palliative operations other than gastrectomy have decreased, in the cases of gastrectomy, there is

little change in the number of hospital deaths, and many more patients live up to four years after operation, and the over-all number of five-year cures has increased from about 5 per cent to 7 per cent.

It is clear that the great increase in the number of gastrectomies is due to the more widespread use of resection as the best palliative operation, even if all gross disease cannot be removed. The increased number of palliative resections has maintained the over-all mortality for resection at the same level as that of the previous study.

A further analysis of the gastrectomies performed is presented in Figure 3. There were no five-year survivals in the patients who had gross disease left in the abdomen, and only a rare five-year survival after total gastrectomy. Practically all the favorable cases fell into the group of subtotal resections, in which all gross cancer is removed.

The statement has sometimes been made that, even if gross cancer is left behind in the abdomen, a cure may result. Our information lends no credence to that claim. Eighty-five per cent of the patients with palliative subtotal gastrectomy were dead a year after operation, and all were dead two years after operation. The average postoperative length of life was about eight months.

Since the average length of life after exploratory laparotomy alone for cancer of the stomach is about six months, palliative gastric resections cannot be defended on the basis that a significant pro-

FIGURE 3. Duration of Life after Various Types of Gastric Resections for Cancer (1937-1941).

longation of life results. On the other hand, patients who have had an obstructing lesion removed are usually more comfortable and may die a relatively painless death from hepatic or pulmonary metastases. Since some patients without hope of cure are condemned to life for a period after operation, such a resection is really palliative. It seems justifiable to continue the use of the term "palliative gastrectomy" to distinguish operations in which gross disease is left behind in the abdomen.

Livingston and Pack<sup>4</sup> have used the term "resectable cancer of the stomach" to describe cases in which all gross cancer can be excised. This is a valuable term, and in the present study is represented by all the subtotal resections, total resections and those done by the transthoracic route in which all gross disease can be removed. In the present series, the mortality for "resectable cancer" is 19 per cent, and the five-year curability is 20 per cent.

The prognosis of any case of carcinoma of the stomach may be gauged fairly accurately by microscopic examination of the specimen. The presence of metastasis to the regional lymph nodes is very

FIGURE 4 *Metastasis and Postoperative Duration of Life after Gastric Resection for Cancer*

*The end-results of all survivals indicate the importance of metastases in the determination of prognosis*

grave. Thus, in the years 1937 to 1941, there were 73 operative survivors who had metastases. Only 4 patients, or 5 per cent, lived five years. On the other hand, of the 42 patients who survived operation and had no extension to the regional nodes 20, or about 50 per cent, lived five years (Fig 4).

#### DISCUSSION

Livingston and Pack,<sup>4</sup> in their very complete survey of the treatment and end-results of gastric cancer, present many figures that are interesting to compare with this present series. It must be pointed out that their monograph was published in 1939 and that all clinics have improved their results since then. Thus, Pack<sup>22</sup> has recently reported that the operability in the Memorial Hospital has risen to 50 per cent. Therefore, no special credit need be taken by the Massachusetts General Hospital, except to point out that, here as well as elsewhere, modest gains have been registered in the therapy of cancer of the stomach.

Livingston and Pack state that there is no report in the literature in which the resectability was over 36.4 per cent and that the average rate was 18.7 per cent. Marshall and Welch,<sup>23</sup> in a recent report from the Lahey Clinic, found that 24.1 per cent of all patients with a diagnosis of cancer of the stomach in the years 1936 to 1940 had a resection. Somewhat similar figures were reported by Counseller<sup>24</sup> from the Mayo Clinic, where resection is carried out in 30 per cent of the patients with a diagnosis of gastric cancer. In our series, 50 per cent had resections, in 16 per cent inaccessible gross disease was left behind, whereas in 34 per cent all gross cancer was excised. The high resectability in this group has contributed to a comparatively high over-all postoperative mortality — 22 per cent. However, during the last five years of the study, although the resectability has increased from 45 to 54 per cent, the postoperative mortality has been reduced to 11 per cent.

Livingston and Pack also found that the average rate of postoperative five-year survivals from surgical treatment in the clinics studied was less than 2 per cent of the patients observed, the best rate reported from any surgical clinic or cancer center has never exceeded 5.2 per cent. In this series, from the years 1937 to 1941 (the last period available for end-results), there were 7 per cent five-year survivals.\*

#### SUMMARY

A study of all the patients with carcinoma of the stomach admitted to the Massachusetts General Hospital during the ten-year period 1937 to 1946 shows that the delay before treatment has remained unchanged, averaging five months. A more aggressive attitude toward gastric ulcer has increased the recognition of early cancer of the stomach.

The introduction of a transthoracic approach and the wider use of total abdominal gastrectomy have increased the number of cases available for resection.

The mortality for gastric resections for cancer has dropped to a present level of 17 per cent for the entire series and to 11 per cent in the last five-year period. The mortality of subtotal resections in which all gross disease is removed has been 3 per cent in the last five-year period.

Meanwhile, the number of unoperated patients has declined so that 75 per cent have an operation. Fifty per cent of the total have a gastrectomy, either subtotal or total.

The best palliative operation, if gross disease cannot be removed, is subtotal gastrectomy.

The five-year survival rate is now 7 per cent of the entire group that enters the hospital.

The most fruitful method now available to increase the number of cures of cancer of the stomach

\*Since this article was submitted for publication, State, Moore and Wangenstein<sup>25</sup> have surveyed the patients with carcinoma of the stomach entering the University of Minnesota Hospital from 1936 to 1945. Their figures show a 55.2 per cent resectability, with a mortality of 16.6 per cent, and an over-all five-year salvage of 6.6 per cent.

is to reduce the delay from onset of symptoms to surgical intervention

## COMPLETE HEART BLOCK\*

### A Study of Two Cases in Veterans of World War II

CHARLES FISCH, M.D.

INDIANAPOLIS, INDIANA

A NUMBER of reports in the medical literature emphasize the fact that some patients with complete heart block may have a favorable prognosis regarding life and the ability to perform daily tasks. In nearly every case the conduction defect is thought to be congenital in origin. Campbell,<sup>1</sup> in his discussion of congenital complete heart block, states that, "if there are no complications carrying special risks of their own, the prognosis is good and will probably prove that the condition is compatible with survival to old age." The cases reported below emphasize the ability of people affected with this malady to lead normal lives and at times to undergo rather strenuous exertion without demonstrable ill effects. Both patients were veterans of World War II. Only 1 case is reported in the literature in which a patient with complete heart block, apparently congenital in origin, was a member of the armed forces.<sup>1</sup>

## CASE REPORTS

**CASE 1.** A 34 year-old man reported to the Out Patient Department on June 11, 1947, for compensation examination because of complete heart block. He had been inducted into the service on December 7, 1943. Preinduction physical examination had revealed a resting pulse rate of 54

rising to 80 on exercise. The remaining examination revealed no abnormalities. After induction he completed 8 weeks of basic training. During a routine screening examination, a systolic apical murmur was heard, and the patient

FIGURE 1. Tracing Obtained in Case 1 on May 15, 1943. Showing Complete Atrioventricular Dissociation with an Atrial Rate between 53 and 60 and a Ventricular Rate of 43. The T waves are upright in Lead I, biphasic in Lead 2, and inverted in Lead 3. The T waves in Lead 4 are upright.

was hospitalized for observation. An electrocardiogram taken on May 15 had shown complete heart block with a biphasic T wave in Lead I, inverted T waves in Leads 2 and 3 and an upright T wave in Lead 4 (Fig. 1). No other

†Resident in medicine, Veterans Administration Hospital.

significant abnormality had been demonstrated during the study. The patient had been discharged from the service on June 5 and had subsequently been employed as a night clerk in a hotel, where he performed general manual labor.

The past history revealed a normal birth after a normal period of gestation. As a child the patient had measles, mumps, chicken pox and pertussis. At the age of 23, while playing baseball, he suddenly fainted. Since that time he had experienced six similar episodes, the last occurring at the age of 28 years. Additional medical history revealed that when the patient was 25 years old he had been told that he had a "bad heart." There was no history of scarlet fever, rheumatic fever, tuberculosis, syphilis or diabetes. The patient had attended school until he was 13 years old. At that time he completed the sixth grade, he incurred no difficulty in learning, but his schooling was stopped owing to the death of his father, whose position as a bread winner the patient accepted. At first he worked as a farm hand and later as a

Fluoroscopic examination of the heart showed the cardiac silhouette to be normal in size and shape.

An electrocardiogram revealed a complete heart block, with a diphasic T wave in Lead I and inverted T waves in Leads 2, 3 and F<sub>4</sub> (Fig 2).

**CASE 2** A 19-year-old veteran reported to the Out-Patient Department for treatment because of "heart trouble" and "weakness."

The patient had been a premature baby and had supposedly weighed only 3 pounds at birth. A further developmental history did not reveal anything unusual. The patient had had measles, mumps, whooping cough and chicken pox. After the period of childhood, except for occasional sore throat, he had never been sick. There was no history of scarlet fever, rheumatic fever, tuberculosis, diphtheria or syphilis. He gave a history of two syncopal attacks, both occurring at the pre-school age. No details concerning these episodes

FIGURE 2 Electrocardiogram Obtained in Case 1 on June 11, 1947, Showing Complete Heart Block. Note the T-wave changes that have taken place since the last observation.

laborer on a railroad. He also held a job in a canning factory and finally was employed as a guard in a defense plant. He had no difficulty performing any of these tasks.

The family history was irrelevant.

Physical examination revealed a well developed and well nourished man who appeared to be in excellent health. The height was 69 inches, and the weight 175 pounds. An exercise-tolerance test, consisting of stepping on and off a chair 18 inches high twenty-five times, caused only a mild dyspnea. Examination of the heart showed no enlargement. There was a Grade I, blowing, systolic apical murmur transmitted only slightly toward the sternum. The murmur was somewhat accentuated by exercise. The remainder of the physical examination disclosed nothing of note.

The blood pressure was 120/80. The resting pulse was 52, rising to 80 after exercise.

Examination of the blood disclosed a red-cell count of 4,450,000 and a white-cell count of 6000, with 66 per cent neutrophils and 34 per cent lymphocytes. The sedimentation rate was 1 mm in 1 hour.

were obtainable. While in school he had no difficulty keeping up with other children. He was a member of the high-school basketball team. After completing 2 years of high school education, he went to work for a packing company. This called for arduous manual labor, which he was able to perform without any ill effects. His next job was that of a truck driver. He subsequently passed a physical examination for a Civil Service position, which he held until his enlistment in the United States Navy on January 5, 1945. Physical examination performed prior to enlistment showed a pulse rate of 48, which increased to 56 with exercise. The remainder of the examination was reported as showing nothing of note. The patient was accepted for duty with the Navy and had no difficulty until April 25, 1945, when he reported to sick bay because of an upper respiratory infection. At the time of admission to the hospital the pulse rate was 44, "increasing only slightly with exercise." A diagnosis of complete heart block was made, the diagnosis being confirmed by a number of electrocardiographic tracings. The patient was discharged from the service on July 10 and subsequently re-

turned to his old job, that of a truck driver. He was unable to perform his duties as well as he did before he entered the Navy because, as he put it, 'he felt weak all over'.

The family history was of no consequence.

Physical examination disclosed a patient of hyposthenic habitus. He did not appear either acutely or chronically ill. An exercise tolerance test consisting of stepping on and off a chair 18 inches high revealed only a mild dyspnea. Examination of the heart disclosed some enlargement to the left, the left border of cardiac dullness being slightly outside the midclavicular line. No thrills were palpable either

rate as compared with acquired complete heart block. The study of the 2 subjects revealed some evidence that may justifiably be construed as indicative of disease of the heart other than the conduction defect. In Case 1 there was an associated progressive inversion of the T waves in Leads 1, 2, 3 and F<sub>4</sub>. This may have been due to some obscure pathologic process, possibly infectious in origin, in-

FIGURE 3. *Electrocardiogram in Case 2 Showing Complete Heart Block, with an Atrial Rate of Approximately 60 and a Ventricular Rate of 33.3. No other significant abnormalities are noted.*

before or after exercise. There was a Grade II blowing aortic murmur, which was best heard in the third and fourth interspaces just to the left of the sternum. This murmur was transmitted toward the apex and was somewhat accentuated by exercise. The remainder of the examination was negative.

The pulse rate was 40, regularly increasing to 52 with exercise. The blood pressure was 140/70.

Fluoroscopic examination showed a mild enlargement of both the right and left ventricles.

An electrocardiogram revealed a complete heart block (Fig. 3).

#### DISCUSSION

It is true that the etiology of the heart block in the cases reported above is open to question. However, the following findings strongly suggested the congenital origin of the conduction defect: the absence of an acquired etiologic agent that is known to affect the myocardium, the ability of the patients to lead normal lives and at times to undergo rather strenuous exertion without demonstrable ill effects, and the presence of a relatively faster pulse

rate as compared with the myocardium or the pericardium, or both, or to a process involving the coronary arteries. No definite conclusion can be reached at present. In Case 2 the systolic murmur coupled with the enlargement of the heart might perhaps be ascribed to the increased stroke volume associated with the slow heart rate.

A review of the literature regarding congenital complete heart block showed a lack of uniform criteria to which a case must conform before it may be assumed to be congenital in origin. Yater,<sup>3</sup> in a review of this subject in 1929, pointed out certain requirements that should be fulfilled before a diagnosis of congenital complete heart block can be made. These are as follows: electrocardiographic proof of heart block, a record of a slow pulse at an early age, and absence of a history of infection, especially diphtheria, rheumatic fever, chorea or congenital syphilis. He also stated that syncope

attacks at a fairly early age and the presence of other congenital heart lesions add weight to the congenital etiology of the heart block. Most writers assume that complete heart block in children and young adults is to be considered infectious in origin until proved otherwise. Recently, different ideas were expressed.<sup>1,3</sup> Leys<sup>4</sup> points out that permanent complete heart block following infection is rare and also states that the burden of proof lies on the shoulders of the one who assumes that a case of complete heart block in young adults is due to infection. White<sup>5</sup> asserts that permanent heart block following an acute infectious process is rare and that the most frequent cause of complete heart block is coronary-artery disease. Campbell,<sup>6</sup> in a review of 64 cases of complete heart block, found that 13 per cent were congenital in origin, and slightly over 10 per cent could be accounted for by syphilis and rheumatic fever. Seventy-five per cent of the cases were due to coronary-artery disease.

Subjective complaints caused by congenital complete heart block are few. A small percentage of the patients experience Stokes-Adams attacks or shortness of breath, or both, on moderate exertion. Others develop neurasthenia after learning about their malady.

Yater<sup>2</sup> calls attention to the relative infrequency of cyanosis in these patients. When cyanosis is found, it is probably due to an accompanying heart lesion rather than to the heart block per se. Physical examination usually reveals a pulse rate of 40 to 50 and an enlarged heart. This cardiac enlargement may be attributed to an associated heart lesion or to prolonged diastolic filling due to slow heart rate.

It is of great practical importance to differentiate congenital complete heart block from the acquired condition, for the prognosis for life and the capacity to lead normal lives is good in congenital heart block. In a series of 8 cases that Campbell<sup>1</sup> followed for nine years he reported 2 deaths. The average sur-

vival rate for the other 6 patients was twenty-two years on last examination. The ages of these patients ranged from twenty-two to forty-two years. Jaleski and Morrison<sup>7</sup> reported a case in a thirty-one-year-old woman with congenital complete heart block who went through two terms of pregnancy and delivery without any complications. Levine<sup>8</sup> mentions a fifty-five-year-old patient who was known to have had complete heart block since the age of six, probably of congenital origin. The optimistic outlook in congenital complete heart block mentioned above should be contrasted with life expectancy in acquired heart block. The studies of Campbell<sup>6</sup> and Graybiel and White<sup>9</sup> show that approximately 70 per cent of patients with acquired heart block died less than three years after the discovery of the lesion. The remaining 30 per cent were alive after an average of six to seven years.

### SUMMARY

Two cases of complete heart block, probably congenital in origin, in veterans of World War II are presented.

The significant clinical aspects of congenital complete heart block are discussed.

## VACCINATION AGAINST INFLUENZA A AND B\*

## A Comparison of Reactions, Doses and Titer Responses of Two Different Vaccines in Infants and Children

R I LIENKE, MD,† E. PERRY CRUMP, MD,‡ AND JOHN M. ADAMS, MD§

MINNEAPOLIS, MINNESOTA

ALTHOUGH numerous investigators have reported success in protecting adults from influenza A and B, very few studies are available in infants and children. A quantitative evaluation of the titer responses in this age group to various doses and types of vaccines was undertaken, as well as a study of the local and systemic reactions

## METHOD

The inoculations of vaccine were given subcutaneously from 9 to 10 a m. Temperatures were taken at four-hour intervals, and changes were computed by comparison with the patient's previous temperature record. The maximum rise was

TABLE 1 Temperature Elevations

‡3 F or higher

to the vaccines. Adams, Thigpen and Rickard<sup>1</sup> showed that the immune response to influenza A infection was equally great in young infants and older children.

A group of 245 children, ranging in age from one to sixteen years and interned in one building for residua of poliomyelitis, were the subjects of this study. The children were divided into five groups, all of which were nearly comparable in age distribution. The first two groups received 0.5-cc and 1-cc doses of vaccine 1 ¶. The second two groups received the same doses of vaccine 2 ||. The fifth group was not vaccinated, but early and later serum titer studies were done as in the first four groups. This study was carried out in November and December, 1946.

determined in each of 186 cases, as well as the mean maximum for each group.

The local reaction was evaluated immediately, and at intervals of approximately twenty-four hours for thirty days.

Samples of blood were obtained before the vaccine was given and fourteen days after its administration. The viruses used in the quantitative titer determinations were those of influenza A (PR 8 strain) and influenza B (Lee strain). The photoelectric densitometer was employed after the method described by Hirst and Pickels.<sup>2</sup> All the four hundred and fifty-six determinations were done in pairs and in large lots.

## RESULTS

## Temperature

The means of the maximum temperature elevations are presented in Table 1. The values show that 0.5 cc of a vaccine gave the same average temperature rise as 1 cc of the same vaccine. Vaccine 1 caused a significantly higher temperature response than vaccine 2. Many children receiving the former had temperatures well over 100°F. The maximum temperature elevation occurred most frequently eight to twelve hours after vaccination.

## Local Reaction

The infection of vaccine 1 caused a sharp, stinging

¶Associate professor of pediatrics, University of Minnesota Medical School.

¶This vaccine, which was prepared from egg cultures of influenza A (PR 8 and Wells strains) and B (Lee strain) viruses by erythrocyte adsorption and elution was kindly supplied by Eli Lilly and Company, Indianapolis, Indiana.

||This vaccine, which was prepared from egg cultures of influenza A (PR 8 and Wells strains) and B (Lee strain) viruses by calcium phosphate adsorption, was kindly supplied by Parke, Davis and Company, Detroit, Michigan.

Vaccine 2 caused little or no immediate pain. The local reaction was measured and palpated at intervals, and although there was considerable variation, the following general observations were made twenty-four hours after the injection of vaccine 1: there was a small area (1 or 2 cm) of erythema,

TABLE 2 Frequency of Systemic Reactions to Influenza Vaccine

VACCINE	DOSE cc	TOTAL NO OF SUBJECTS	SUBJECTS WITH REACTIONS	
			NO	PERCENTAGE
1	0.5	39	11	28
2	0.5	48	3	6
1	1.0	49	10	20
2	1.0	48	8	17

which was slightly swollen and indurated and moderately tender. At forty-eight hours there was usually minimal or no local reaction remaining. Twenty-four hours after the administration of vaccine 2 there was an area of erythema, which, on the average, was significantly larger (2 to 10 cm) than that caused by vaccine 1. Also, the local site was usually more swollen and indurated, and in a

quent, reactions were observed with vaccine 1. The least number of systemic reactions occurred with 0.5 cc of vaccine 2. A convulsion occurred in a one-year-old girl who received 1 cc of vaccine 1.

No unquestionably positive reaction was observed in any of the 60 children who were given skin tests. Difficulty in interpreting skin tests with the undiluted vaccine was encountered because of the irritative properties of the formalin contained in the material used. (None of these subjects are included in the titer studies.) Curphey<sup>3</sup> has reported a fatal allergic reaction to influenza vaccine. Ratner and Untracht<sup>4</sup> cited several allergic reactions and recommend that all patients be tested with 0.02 cc of the undiluted vaccine before vaccination. Protamine-precipitated vaccine,<sup>5</sup> like that of calcium phosphate adsorbed, apparently contains less allergenic substance than the vaccine prepared by erythrocyte adsorption. A newer vaccine prepared by centrifugation<sup>6</sup> is said to be virtually free of substances causing allergic reactions.

### Antibody Titers

The increase in the antibody titer is indicated by the ratio of the late to the early value rather than

TABLE 3 Frequency Distribution of Titer Ratios

VACCINE	DOSE cc	INFLUENZA VIRUS	SUBJECTS WITH INCREASE OF LATE OVER EARLY TITER				TOTAL NO OF TITER PAIRS	GEOMETRIC MEANS OF INCREASES
			LESS THAN 2 FOLD	2 TO 3.9 FOLD	4 TO 7.9 FOLD	8 TO 50 FOLD		
1	0.5	A	14	3*	7	3	27*	2.4 fold
2	0.5	A	14	5	1	2	22	3.5 fold
1	0.5	B	8	8	6	5	27	1.9 fold
2	0.5	B	9	7	2	4	22	2.9 fold
1	1.0	A	11	7	3	1	22	2.1 fold
2	1.0	A	5	3	4	2	14	4.1 fold
1	1.0	B	4	6	6	5	21	3.0 fold
2	1.0	B	1	2	3	7	13	7.8 fold
(Control)		A	30	0	0	0	30	1.0 fold
(Control)		B	30	0	0	0	30	1.0 fold†

\*Of the 27 titer pairs against influenza A in the group receiving 0.5 cc of vaccine 1, there were 3 with late titers showing an increased range of 2 to 3.9 fold over the early titers.

†1.0 fold represents no increase in the late over the early titer.

few subjects the whole upper arm was tender. At the end of forty-eight hours a definite subcutaneous nodule had formed in most of the subjects receiving vaccine 2. This was still present thirty days later in a few cases.

### Systemic Reactions

The number of systemic reactions is recorded in Table 2. The ages of the children with reactions ranged from thirteen months to nine years in the group given 0.5 cc of vaccine 1, three to thirteen years in the group given 0.5 cc of vaccine 2, sixteen months to sixteen years in the group given 1 cc of vaccine 1 and two to fifteen years in the group given 1 cc of vaccine 2. The principal reactions were headache, restlessness and wakefulness. In general it was concluded that severer, as well as more fre-

quent, reactions were observed with vaccine 1. Table 3 shows the frequency distribution of all the cases in terms of the number of fold increase of the late titer over the early titer (late to early ratio).

In view of the fact that the titers increase in a geometric fashion, the geometric mean was employed in the group comparisons, and the statistical calculations were made on the basis of logarithms. The geometric means for the titer increases are included in Table 3. All the means in the groups receiving vaccine were significantly higher than those in the control group. Except for the mean increase of 7.84 against the virus of influenza B in the group receiving 1 cc of vaccine 2, in which the number of patients was too small and the range of values too great to justify an accurate comparison, there was no significant difference

between the groups. For example, 1 cc of a vaccine was no better than 0.5 cc of the same vaccine, nor was vaccine 1 better than vaccine 2 from this point of view. There did not appear to be any differences in the titer response of the younger compared to the older children. The titers against the virus of influenza B were generally higher than those against the virus of influenza A.

### DISCUSSION

The subjects in our study were not exposed to an epidemic of influenza, so that the value of the vaccinations was not tested clinically. A fairly consistent rise in antibody titers was demonstrated in the majority of the vaccinated group as opposed to the controls. Henle, Henle and Stokes<sup>7</sup> have shown greater protection against the disease in the persons with the high titers. The majority of the subjects whose titers failed to rise appreciably (less than twofold) had high initial levels.

All the inoculations were given subcutaneously. Van Gelder and his associates<sup>8</sup> concluded that the intracutaneous route produced better titer responses. No subject in our study received more than one injection. The antibody level reached after one dose was as high as that observed after two doses according to a study reported by Hare and his co-workers.<sup>9</sup>

The second blood sample was drawn after fourteen days in all subjects. These titers probably did not represent the maximum level in each case because of varying host responses as well as the differences in vaccines used.

In our experience, the vaccines employed were safe for infants and children in the doses employed, and with one exception, in which a large dose was given to a one-year-old child, no severe reactions were observed in the 245 subjects. The question of the use of influenza vaccine in the practice of medicine remains for the individual physician to answer. Certainly, it may be offered as giving protection of some degree to most persons, since its value has now been attested by several reports, including that of the Army Influenza Commission.<sup>10</sup> The administration of any vaccine entails an occasional unfavorable reaction. Whether or not this militates against its use in practice cannot be decided here, but its value as a public-health measure can hardly be questioned when the morbidity and mortality figures in large cities after influenza epidemics are studied. The uncomplicated disease except for pandemics probably is not responsible for death, but it is one of the common precursors of

pneumonia, which takes its toll after every influenza epidemic. The pandemics of influenza recorded in medical history have been responsible for more deaths than any scourge known to man. One of the probable causes of pandemics is a world-wide susceptibility. It seems possible that extensive use of influenza A and B vaccine will offer man some protection against pandemic as well as epidemic influenza and against the high mortality associated with this disease.

### SUMMARY

A comparative study of reactions, doses and antibody titers has been made with two different vaccines against influenza A and B in infants and children.

The temperature elevations were significantly higher with vaccine 1 than with vaccine 2, although the dose of the vaccines did not appear to make any appreciable difference. Vaccine 2 caused more local reactions, such as swelling and tenderness at the site of inoculation, whereas the systemic reactions appeared to be more intense with vaccine 1.

A definite increase in the antibody titers was demonstrated in the majority of the vaccinated subjects as compared to the controls, but no significant difference between the vaccines was observed.

There was no significant difference between the titers obtained with 0.5 cc and 1 cc of the same vaccine. Children under three years of age, in our opinion, should not be given more than 0.5 cc of vaccine.

The decision whether or not to use influenza vaccine is left to the individual physician.

ACUTE MENINGITIS CAUSED BY *NEISSERIA SICCA*\*

CHARLOTTE BANSMER, M.D.,† AND JACOB BREM, M.D.‡

NEW ROCHELLE, NEW YORK, AND WORCESTER, MASSACHUSETTS

THE gram-negative diplococci such as *Neisseria catarrhalis* and *N. sicca*, commonly found in the pharynx, rarely cause meningitis. However, upon occasions they have been proved to be the sole cause of the disease.<sup>1-10</sup> The following case of meningitis due to *N. sicca* was proved by culture and serologic examination §

R. L., a 6½-year-old boy, entered the hospital on January 20, 1947, with a history of sore throat, frontal headache, fever and vomiting of 24 hours' duration. The temperature had risen to 104°F, the headache had increased in severity and he had developed a stiff neck a few hours before admission. The patient had received several doses of sulfadiazine at home, but most of this had been lost in the vomitus.

The past and family histories were noncontributory except for left internal strabismus since infancy.

Physical examination revealed a well developed and well nourished child, who was drowsy but conscious and co-operative. There were no abnormal eye findings except for the left internal strabismus. The fundi were normal. Definite spinal and nuchal rigidity were elicited. The mucous membrane of the throat was somewhat inflamed. The ears were normal. The posterior cervical lymph nodes were slightly enlarged. No petechiae were noted. A bilateral Kernig reflex was present. The blood pressure was 100/70.

Examination of the blood showed a red-cell count of 3,930,000 and a white-cell count of 15,200, with 86 per cent neutrophils, 12 per cent lymphocytes and 2 per cent eosinophils. A blood culture was negative, as was a tuberculin patch test. An x-ray film of the chest was normal. The blood sulfadiazine level ranged from 9 to 15 mg per 100 cc. A lumbar puncture was done and 10 cc of cloudy spinal fluid, under increased pressure, was obtained. The initial pressure was equivalent to 280 mm of water, the dynamics were normal. Examination of the spinal fluid disclosed a white-cell count of 4150, with 84 per cent polymorphonuclear leukocytes, 16 per cent lymphocytes and a total protein of 80 mg, sugar of 83 mg and chloride of 720 mg per 100 cc. A direct smear demonstrated many pus cells but no organisms, a culture showed *N. sicca*.

As soon as the diagnosis of meningitis had been established the patient was given sodium sulfadiazine intravenously and penicillin intramuscularly. Because the previous vomiting had resulted in some dehydration, 5 per cent glucose in physiologic saline solution with 1/6 molar lactate was given intravenously. In the evening of the 2nd hospital day, the urine was noted to be grossly bloody, and sodium sulfadiazine was therefore discontinued. Streptomycin (125,000 units every 3 hours) was started, and 1/6 molar lactate was continued intravenously to keep the urine alkaline — 24 hours later the urine was free of blood.

On the day after admission the patient showed considerable improvement, and he was able to retain food. Penicillin was given intrathecally (5000 units in 5 cc of physiologic saline solution) on the 2nd and 3rd days. The urine contained red cells on the 3rd hospital day but was normal thereafter. On the 4th hospital day, there were no clinical signs of meningitis. Streptomycin was discontinued, and at that time oral glucosulfadiazine was given without any further untoward effect. The patient continued to improve. Penicillin was discontinued on the 9th, and glucosulfadiazine on the 11th hospital day. The spinal fluid on discharge was

clear, with 4 white cells per cubic millimeter, 100 per cent lymphocytes, a sugar of 49 mg per 100 cc and a total protein of 36 mg per 100 cc, culture was negative.

Serum agglutination with *N. sicca* demonstrated a positive titer in a dilution of 1:384 (control, negative) 12 days and one of 1:384 (control 1:96) 61 days after the onset of the acute illness. The titer was negative for both patient and control 154 days after the onset.

## DISCUSSION

The initial diagnosis in this case was meningococcal meningitis, in view of the presence of clinical meningitis with cloudy spinal fluid, which on direct smear showed many pus cells but no organisms. The diagnosis was further strengthened by the report of the presence of a gram-negative diplococcus obtained from the culture of the spinal fluid. However, the laboratory soon reported that the organism isolated did not agglutinate with any of the strains of meningococci available. Subsequently, this organism was identified by the laboratory of the Worcester Public Health Department and confirmed by the laboratory of the Massachusetts Department of Public Health as *N. sicca*.

The possibility of contamination of the spinal fluid was entertained, but on inquiry it was found that this organism is a very rare contaminant.<sup>11</sup>

The question of determining whether the patient had developed immune bodies to this organism was then investigated. Because *N. sicca* tends to clump spontaneously in the presence of physiologic saline solution, the antigen was prepared by a special method to minimize this phenomenon. The organism was grown on nutrient agar slants and incubated at 35°C for forty-eight hours. The slants were washed off with tap water as a precautionary measure to avoid automatic precipitation of the organism. The harvest was collected and ground up with fine sand,<sup>12</sup> and the suspension was allowed to stand for one hour. The supernatant fluid was decanted through cotton, and the suspension diluted with tap water to a No. 8 McFarland nephelometer standard of approximately 2,400,000,000 organisms per cubic centimeter. The antigen was then killed at 60°C for one hour. No preservative was added. The routine slow macroscopic tube agglutination test was used, as described by Kolmer and Boerner.<sup>13</sup> Inasmuch as there was a small but definitely noticeable amount of antigen precipitation in tap water, a positive reaction was assigned only to tubes that showed marked clearing with the formation of large flakes.

It will be noted that twelve and sixty-one days after the onset of acute symptoms, the organism

<sup>13</sup>Suggested by Dr. Raymond H. Goodale, pathologist, Worcester City Hospital.

was agglutinated by the patient's serum in a dilution of 1:384. Approximately five months after the illness the titer had dropped to a normal level. The control serums were presumed to be normal and were obtained from men between the ages of twenty and twenty-three years. The finding of a titer of 1:96 in one of the control serums cannot be definitely explained, except by the fact that the control subject may have had a recent infection with *N. sicca*.

On review of the literature it was found that meningitis due to *N. sicca* has been reported only in the course of an endocarditis caused by this organism.<sup>5-7, 10, 12</sup> In the 5 reported cases of endocarditis, symptoms of meningitis occurred in 3, and a positive spinal-fluid culture was found in 1.<sup>7</sup> All these cases of endocarditis terminated fatally except 1 in which recovery followed the use of heparin and sulfapyridine.<sup>6</sup>

Several cases of meningitis caused by *N. catarrhalis* have been reported<sup>11, 9</sup> and also some cases caused by atypical *Neisseria*.<sup>2, 3, 4, 8, 10</sup> The comparative rarity of meningitis caused by this group of organisms suggests a low pathogenicity but modifies the older concept of this group as non-pathogenic.<sup>14</sup>

#### SUMMARY

A case of acute meningitis caused by *Neisseria sicca* is reported. The organism isolated was identified by two different laboratories. An attempt was made to determine the titer of antibodies in the

patient's serum, cultures of the organism being used as the antigen. Although the serologic method available was not entirely satisfactory because of the characteristics of this organism to clump spontaneously, significant titers indicating antibody formation were obtained. Approximately five months after the onset of the acute disease, the titer had dropped to a normal level.

It is believed that this is the first straightforward case of acute meningitis caused by *N. sicca* and uncomplicated by any other infectious process such as endocarditis described in the literature.

## MEDICAL PROGRESS

### CANCER

GRANTLEY W TAYLOR, M D \*

BOSTON

AS a result of public interest, large sums of money have become available in the field of cancer, from state and federal sources and from charitable foundations, and it seems probable that the interest and funds will continue for a long time. The money has been used for stimulation of research, for cancer education among the laity and the medical profession and for direct service to the patient in the form of improved diagnostic and therapeutic facilities.

#### RESEARCH

The literature of laboratory cancer research has become so voluminous that it is virtually impossible for anyone to undertake to digest it all. The Fourth International Cancer Research Congress presented representative contributions in all the principal fields of investigation. Cowdry's<sup>1</sup> recent summary of the Congress ably recapitulates the major fields of interest.

#### EDUCATION

##### *Undergraduate*

Although a considerable part of a medical-school curriculum deals with cancer, and with basic sciences essential to an understanding of cancer, it is true that in many medical schools there has been little or no attempt to correlate the various components in such a way as to give the student a coherent conception of cancer. A committee of the National Advisory Cancer Council has urged the desirability of co-ordinating the teaching of cancer in medical schools, offering financial support for schools presenting acceptable plans of instruction. Several schools have already adopted the recommendations of the committee, and it is anticipated that others will recognize the merits of the proposals.

##### *Graduate*

Fellowships offered by the National Advisory Cancer Council are intended to train men at the resident level to be cancer specialists. The rather rigid requirements of training in surgery, radiology and pathology make it difficult for many hospitals to fit these fellowships into existing resident training programs. In addition, the fellowships come into conflict with the requirements of many of the specialty certification boards. Some relaxation and

elasticity of the program would probably result in better training of more men.

The American College of Surgeons, at the annual clinical congress and in the sectional meetings, offers special sessions and symposia in cancer. These meetings bring to a large audience a condensed review of recent important advances in the cancer field. The series of special articles appearing in the *Journal of the American Medical Association*,<sup>2</sup> with the co-operation of the American Cancer Society, is designed to bring a concise presentation of cancer subjects to the general practitioner. These articles will be assembled in a book, which will assure their preservation.<sup>3</sup> The announcement of a new journal *Cancer*, under the sponsorship of the American Cancer Society, to include a thorough abstract section in addition to original contributions, is welcome news to all who are working in this field.

##### *Public*

Lay education in cancer has been promoted by various groups, notably by the Women's Field Army of the American Cancer Society. There can be no question that as a result of such education, many patients seek medical advice earlier than they would have done otherwise. They are also likely to require a more thorough examination from their physician. Indeed, the demands of the laity have emphasized the necessity for improved cancer teaching for the profession. The public interest stimulated by lay education has in large measure helped to make available the funds referred to above, and to some degree has given the laity a voice in the projects for which the money is used. The public demand has also been responsible for the development of detection clinics.

#### DETECTION CENTERS

It is a basic postulate that the earlier a cancer is detected and treated, the greater is the likelihood of cure. It is also true that the earliest stages of most cancers give rise to no symptoms. Thus, it would be desirable to have some test to which the apparently healthy person could be submitted that would detect cancer in its earliest stages. The only present test that can be employed is a complete and thorough examination. The more thorough the examination, the greater is the likelihood that cancer will be detected in its early stages. Practical considerations of time, personnel and expense impose

\*Associate in surgery, Harvard Medical School, visiting surgeon, Massachusetts General Hospital, visiting surgeon, Pondville Hospital.

limitations on the thoroughness of the examination. It is apparent that the initial examination must be relatively brief and inexpensive, and that this preliminary screening may be expected to segregate for more extensive study the group most likely to show positive findings.

In regular medical practice the most significant finding on screening is the presence of a symptom or symptoms. Indeed, a patient in general exercises this screening test and consults a physician or goes to a clinic because of a symptom. The physician can then carry out the more thorough investigation necessary to discover the cause of the symptoms. In doing so, he may uncover cancer or some other disease. Without the stimulus of symptoms to be explained, examinations may become perfunctory or routine. Statistics must be available regarding the number of cases of cancer found during the routine physical examinations of applicants for life insurance or of men selected for military service. Statistics are available concerning the expected incidence of cancer in various age groups at a given time.<sup>4</sup>

In response to public pressure, under the sponsorship of various foundations, numerous centers have been established for the detection of cancer. The American College of Surgeons has defined standards for these centers and gives approval to those complying with the standards.<sup>4</sup> Most of the centers report a much higher incidence of cancer than the calculated expected frequency.<sup>6</sup> It is probable that this is due to the inclusion of a large number of persons who are not in fact free from symptoms, and that the centers are serving to this extent as cancer clinics rather than as detection centers.

The centers also reveal a very great number of other conditions requiring medical treatment.<sup>7</sup> These findings may be compared with the number of rejections for physical reasons of men selected for military service. Proponents of the centers consider that many of the nonmalignant conditions encountered are precancerous, and that prompt attention to them prevents the development of cancer. This viewpoint involves a rather broad concept of precancerous conditions.

Although it is premature to evaluate cancer-detection centers, the experiences should be dispassionately reviewed from the standpoint of expense of operation in relation to cases found at a significantly early stage. Follow-up studies of the cases with negative findings should give information regarding the number of cases overlooked. It may well be found that greater numbers of early cancers can be found with less expense of time and money, by intensified education of the laity to report early symptoms and of the medical profession to evaluate these early symptoms.

#### DIAGNOSIS

Interest in cytologic methods of diagnosis from smears continues unabated,<sup>8-11</sup> although many

orthodox pathologists preserve a commendable reluctance to accept the findings without reservation.<sup>12</sup> The application of this technic to permit early evaluation of the efficacy of radiation treatment of carcinoma of the cervix, proposed by Graham,<sup>13</sup> may prove to be valuable in the selection of cases requiring surgical intervention. A series of 280 aspiration and punch biopsies was reported by Ellis,<sup>14</sup> with "useful results" in 63 per cent. Meatheringham and Ackerman<sup>15</sup> reported 300 aspiration biopsies on lymph nodes. In 69 aspirations no lymphoid tissue was obtained. A positive diagnosis of carcinoma was made in 147 specimens, and cancer subsequently developed in 32 cases in which the aspiration specimen was negative. Several authors express a warning against aspiration biopsy in possibly operable lung tumors, because of the danger of pleural implantation. Isaacson and Rapoport<sup>16</sup> reported a series of 34 cancer patients who presented an eosinophil count of more than 10 per cent. It is not generally realized that this degree of eosinophilia may be caused by cancer. In 90 per cent of cases multiple metastases were present.

#### LYMPHATIC SPREAD

There has been considerable interest in recent years in amplifying and confirming knowledge of the pathways of lymphatic spread. The brilliant studies of Gilchrist and David<sup>17</sup> on the lymph-node metastases of carcinoma of the colon and rectum have greatly influenced the concept of the radical operations for dealing with these cancers. Similar methods of study were employed by Coller, Kay and MacIntyre<sup>18</sup> in cancer of the stomach, colon and rectum. Sweet<sup>19</sup> has contributed to knowledge of the lymphatic spread of carcinoma of the esophagus. Warren and Tompkins<sup>20</sup> have drawn attention to the correlation between prognosis and the numerical extent of lymph-node metastases. Whereas it is generally conceded that lymph-node involvement is usually embolic rather than by permeation, it is evident that the concept of permeation frequently influences the plan of operation, and it remains true that removal of the regional lymphatic vessels en bloc along with the primary focus is an ideal cancer operation when it is feasible.

#### SURGICAL TREATMENT

Critical review of autopsy material discloses that in many cases death from cancer is due to the local extension of the disease, with interference with the functions to adjacent normal organs, rather than to widespread metastatic involvement. Realization of this fact, in conjunction with the general lowering of mortality and morbidity after radical surgery, has led to increasingly radical operative procedures to cope with advanced stages of local disease. Although these operations are too recent to permit evaluation of long-term cures, they offer the possi-

bility of cure in many cases hitherto regarded as inoperable, and in most cases find justification at least as effective palliative procedures. While Brunschwig has written extensively on this subject, the tendency is evident in almost all fields of cancer surgery.

### ORAL CANCER

No single report indicates the trend in the field of oral cancer, but many surgeons are reviving the concept of a one-stage operation for lesions of the tongue, floor of the mouth and cheek, with simultaneous neck dissection and, when necessary, resection of the jaw. These operations can be applied to some cases considered inoperable by conventional standards. Since the procedures are based upon the concept of spread by permeation, which is not the usual method of lymphatic involvement from these cancers, in many cases they show no advantage over the two-stage operations currently practiced. In addition, in coping with inoperable intraoral lesions, they must demonstrate results more satisfactory than those now obtainable by intensive radiation. Although these radical operations undoubtedly have a place, it is likely that their field of employment will be a restricted one.

### CERVICAL-LYMPH-NODE METASTASES

There has been increased willingness on the part of certain surgeons to carry out radical neck dissections bilaterally, with a short interval between the two sides. This procedure involves sacrifice of both internal jugular veins, as well as the anterior and external jugular veins, and is not without danger of causing cerebral damage. In most cases it is probably safer to preserve the internal jugular vein on one side, and it is usually possible to do so. Sugarbaker and Gilford<sup>23</sup> recently drew attention to the combination of neck dissection and jaw resection in cases in which lymph nodes present fixation to the mandible. This procedure has been employed in many clinics, and the dangers of postoperative complications of shock, hemorrhage, sepsis and pneumonia have diminished.

### CARCINOMA OF THE LARYNX

New et al<sup>24</sup> have reported the excellent results obtained by radical surgery in carcinoma of the larynx. Whereas it is true that many of the early cases are amenable to radiation therapy, there is agreement that laryngectomy is the procedure of choice in more advanced cases,<sup>25, 26</sup> and there is evidence that subradical surgical procedures are more effective than radiation in most early cases.

The possibility of training patients in esophageal use of the voice makes laryngectomy more acceptable. Brunschwig<sup>27</sup> has carried out very radical laryngectomy for advanced disease, removing regional lymph nodes and any other structures that may be implicated in the spread of the disease.

### CARCINOMA OF THE LUNG

Most authors recognize the desirability of removing enlarged lymph nodes in the vicinity of the hilus, along with the entire lung, in carcinoma of the lung. In addition surgeons have not hesitated to resect invaded areas of pericardium, parietes or other adherent structures. Although no cures have been obtained by these radical extensions, the operations at least fulfill the desideratum of leaving no obvious disease behind.<sup>28, 29</sup>

There has been increased recognition of the feasibility and desirability of carrying out pulmonary resection for solitary metastasis of sarcomas and carcinomas, and occasionally long-term arrests or even cures are effected.<sup>30</sup>

### CARCINOMA OF THE ESOPHAGUS

The extent of operations for esophageal carcinoma has increased, with better understanding of the intramural and lymphatic spread of the disease. In this field also Brunschwig and Camp<sup>31</sup> have described a very radical extirpation of the total cervical esophagus. Garlock<sup>32</sup> and Sweet<sup>33</sup> have contributed to elucidation of the technical problems of resections.

### CARCINOMA OF THE STOMACH

Coller's<sup>34</sup> studies of metastases have emphasized the desirability of more radical operations for carcinoma of the stomach. Longmire<sup>35</sup> and Wahren<sup>36</sup> have advocated total gastrectomy as a better operation for cancer than subtotal gastrectomy. However, the mortality from total gastrectomy still remains relatively high,<sup>36</sup> and the survivors, even those who are cured of cancer, may be significantly impaired in health.<sup>36</sup> All authors emphasize the urgent need for earlier recognition<sup>37</sup> and for a radical approach to the problem of gastric ulcer.<sup>38, 39</sup>

### MISCELLANEOUS ABDOMINAL CARCINOMAS

In the field of multiple and apparently inoperable abdominal carcinomas, Brunschwig<sup>40, 41</sup> has reported a brilliant series of radical improvisations, as well as modifications of operative technic in carcinomas of the pancreas and duodenum.<sup>42</sup> Resections of the liver for primary carcinoma were reported by Hoyne and Kernohan<sup>43</sup> and by Duckett and Montgomery.<sup>44</sup> Rabinovitch et al<sup>45</sup> described a series of sarcomas of the intestinal tract. Ehrlich and Hunter<sup>46</sup> reviewed the experience of the Army Institute of Pathology in tumors of the gastrointestinal tract.

### CARCINOMA OF THE RECTUM

The same unwillingness to accept local fixation as a contraindication to radical operation applies to carcinoma of the rectum. Bricker<sup>47</sup> presented a number of cases in which parts of the male genitourinary tract were included in the resection, even to the extent of total removal of the bladder,

prostate and vesicles, with transplantation of the ureters into the proximal portion of the bowel. In the female patients it is not unusual to include the uterus and posterior vaginal wall in the resection.

### CARCINOMA OF THE CERVIX

There has been a revival of interest in the radical operation for carcinoma of the cervix,<sup>43</sup> based on the lowered mortality and recognition of the inadequacy of radiation in the control of lymph-node metastases. This operation has also been extended to include certain cases with local invasion of the bladder or rectum or both.<sup>44</sup> The successful outcome of such an operation—total cystectomy, total hysterectomy, lymph-node dissection, abdominoperineal resection of the rectum, vulvectomy, vaginectomy, and bilateral ureteral transplantation—is eloquent testimony to improved technology in surgery.

### CARCINOMA OF THE BREAST

Haagensen<sup>45</sup> has returned to the classic Halsted amputation, with wide skin removal, thin skin flaps and routine skin grafts, in the operation for carcinoma of the breast. Most students believe that this elaborate and meticulous operation is not necessary. Differences in results from various clinics are often attributable to differences in the criteria of operability. Ducuing<sup>46</sup> employs a more radical operation than that usually carried out in this country, removing the fascia of the subscapular muscles and the anterior digitations of the serratus magnus muscle and the subclavius muscle, along with the thoracodorsal and long thoracic nerves. Pickrell et al.<sup>47</sup> described techniques employed in localized resections of the thoracic wall in dealing with operative-field recurrences.

### SARCOMA OF THE EXTREMITIES

Gordon-Taylor and Patey<sup>48</sup> presented a further review of their series of interminominoabdominal amputations, chiefly performed for sarcoma of the upper portion of the thigh and pelvis. Pack and Ehrlich<sup>49</sup>,<sup>50</sup> have also presented a series of radical amputations, in some cases combined with regional lymph-node dissections, for a variety of advanced malignant conditions. Again on the basis of the theory of lymphatic permeation, Pack et al.<sup>51</sup> stated, "In the lower extremity for primary melanoma of the foot metastatic to inguinal and femoral lymph nodes, we resort to a hip joint disarticulation combined with a retroperitoneal dissection of the iliac and obturator nodes." This procedure appears to be excessively radical unless the authors intended to restrict it to certain cases of advanced disease. Haggart<sup>52</sup> reported a series of radical shoulder-girdle amputations in the treatment of primary malignant tumors of the humerus.

### MALIGNANT LYMPHOMA

Hellwig<sup>53</sup> reported a series of cases of localized malignant lymphoma in which radical surgery was employed, with five-year cures in a significant number of cases.

### CASE 34171

#### PRESENTATION OF CASE

A thirty-year-old man, a store clerk, entered the hospital with a complaint of pain in the stomach.

Six months prior to entry the patient noted a dull, heavy, nonradiating, epigastric pain, which occurred in the morning and after meals. It was relieved in part by alkalies and warm milk. There was no nausea or vomiting and no tarry stools, and only a rare stool contained bright-red blood. There had been no anorexia or weight loss. About a week before admission a dull, constant, nonradiating pain in the left flank suddenly developed. Two days prior to admission there was a dull, aching pain in the hypogastrium. This was intermittent in character and resembled the epigastric pain.

Physical examination showed a well developed and well nourished man who was moderately distressed because of hypogastric pain. The lungs were clear to percussion and auscultation. The heart was not enlarged, and no murmurs were heard. There was tenderness in the abdomen to deep pressure, localized mainly just to the left of the umbilicus. Pressure on that area also produced pain in the

back. There was no rebound tenderness. In addition, there was definite costovertebral-angle tenderness on the left and in the region of the left kidney. The liver and spleen were not palpable. There was thought to be a group of matted lymph nodes at the base of the left jugular vein.

Examination of the blood disclosed a hemoglobin of 13 gm and a white-cell count of 8200, with 77 per cent neutrophils. The urine was normal. A stool specimen gave a negative guaiac reaction. The total protein was 7.4 gm, the nonprotein nitrogen 27 mg per 100 cc, the chloride 98 milliequiv per liter, and the serum amylase 16 units.

On the day of admission a gastrointestinal series revealed a 5-cm filling defect on the greater curvature in the prepyloric region. No ulceration was observed, and peristalsis did not pass through the area. A smear and gastric washings showed no malignant cells. An intravenous pyelogram performed on the third hospital day was not entirely satisfactory because of gas and fecal material in the overlying bowel, but demonstrated a delayed secretion of the dye on the left, with a moderate degree of hydronephrosis and hydroureter. Two days later a retrograde pyelogram again showed a left hydronephrosis and some degree of obstruction to drainage of the opaque medium. On the sixth hospital day a gastroscopy showed the greater curvature to be distorted by red, edematous rugae. There appeared to be spasm over this area, and no peristalsis was present. There was a superficial ulceration on the lesser curvature, which measured 1 mm in depth and 1 cm in diameter. The appearance described extended about halfway up the body of the stomach and then ended rather abruptly. On the eighth hospital day the patient vomited reddish-brown material and had severe, colicky pain in the left flank that persisted.

On the twelfth hospital day an operation was performed.

## DIFFERENTIAL DIAGNOSIS

DR DANIEL S ELLIS It seems to me that it is very clear that this patient had disease involving the stomach and left urinary tract, and I judge that the same disease involved both organs and that it was a malignant process of some kind. I do not know what kind of operation was performed—whether he had a biopsy or whether he was operated on with the idea of attacking the stomach or left urinary tract. Perhaps the x-ray films will help in determining the nature of the lesion in the stomach, and also reveal the location of the obstruction in the left urinary tract.

DR STANLEY M WYMAN Examination of the stomach shows the antrum and prepyloric region to be constantly deformed. On the greater curvature there is a constant pressure defect, which elevates the antrum and prepyloric region. The mucosal folds in the lesser and greater curvatures appear unusually thick and prominent. One can see no definite destruction of the mucosa, however. The duodenal loop is not remarkable, but there is deformity of the cap consistent with an old ulcer. The two films from the pyelogram show a slight degree of hydronephrosis on the left with blunting of the minor and major calyces, and widening of the ureter and pelvis. The ureter is traced to the body of the fourth lumbar vertebra. There is no obstruction to that point, and there are no visible stones to account for the dilatation. A single film taken from the retrograde examination shows more clearly the hydronephrosis, which has a generalized character with some delay in the passage of dye at the ureteropelvic junction. No definite obstruction of the ureter can be seen. The kidney outline cannot be adequately detected. The kidney is not displaced in position, and there is no evidence of a pressure defect on the kidney itself. The lung fields and heart are not remarkable.

DR ELLIS Is there any evidence of a soft-tissue mass at the base of the neck?

DR WYMAN No, not in this one film.

DR ELLIS It seems to me that there is no question that if we can ever interpret symptoms as being typical of certain diseases, this patient had a peptic ulcer or ulceration in the stomach, and the original symptom of a dull, nonradiating epigastric pain occurring postprandially early in the morning and relieved by alkalies and warm milk is that of an ulcerating lesion in the stomach. The pain seemed to change very definitely and became hypogastric and related to the region of the left kidney. As far as I am able to determine there are no other clues.

I suppose that a simple peptic ulcer can be fairly well ruled out on the basis that both the gastroscopist and the radiologist who examined the patient thought that there was an extensive lesion involving the lower part of the stomach in the prepyloric

region. Therefore, I believe that this patient had a malignant lesion involving both the stomach and the retroperitoneal lymph nodes and the left ureter, causing hydronephrosis. Such a condition must have been a carcinoma or a lymphoma of some kind. On the law of averages a patient thirty years old ought not to have carcinoma of the stomach, and it is much more likely that he had a lymphoma. The types of lymphomatous disease possibly involving the stomach and the lymph nodes are reticulum-cell sarcoma, lymphosarcoma and, much less likely, Hodgkin's disease. Still another possibility is tuberculosis, of which there seems to be no indication. If this patient's symptoms were first related to the stomach, I think that he had a prepyloric lesion, which was primary in the stomach and metastasized, involving the left urinary tract, causing pressure on the left ureter, with secondary hydronephrosis, and I shall put lymphosarcoma as the first choice. Having had two cases of renal-cell carcinoma before me today, I suppose I am on the spot to say that this is a third case of renal-cell carcinoma, since things usually come in threes. I think that a primary renal tumor with metastases involving the stomach would be less likely than the other way around—that this was a primary carcinoma of the stomach with metastases involving the left urinary tract. I do not believe that this was a scirrhus type of cancer such as one sees in linitis plastica, although it was certainly an infiltrating lesion from the description.

I shall conclude by saying that this man had lymphosarcoma, primary in the stomach, with metastases involving the retroperitoneal lymph nodes and causing partial obstruction and increasing obstruction to the left ureter. And if he really had lymph nodes in the neck I shall interpret them as further evidence of that diagnosis. If he had Hodgkin's disease or leukemia, I would expect to have some clue from the blood smears, but there are none recorded for me to base such a diagnosis on.

DR EDWARD B BENEDET I do not remember this case, but from the description I do not believe it is correct to say that I saw the prepyloric area and described the region of the antrum. As I read the description given, there was an ulcer on the lesser curvature, probably in the body of the stomach.

DR ELLIS It is reported by you and the roentgenologist that no peristalsis was seen in the lower portion of the stomach.

DR BENEDET It probably means that I did not see the antrum and pylorus.

DR ELLIS From the x-ray studies and the way I read this summary I interpret them to signify involvement of the lower end of the stomach by an infiltrating type of lesion.

## CLINICAL DIAGNOSIS

Lymphoma involving the stomach wall and retroperitoneal tissues?

## DR ELLIS'S DIAGNOSES

- Infiltrating malignant tumor of stomach, probably lymphosarcoma, with metastases to retroperitoneal nodes
- Left hydronephrosis secondary to metastatic involvement of left ureter near left renal pelvis

## ANATOMICAL DIAGNOSES

- Mucous carcinoma of stomach, signet-ring type*
- Metastases to mesenteric and retroperitoneal lymph nodes
- Obstruction of left ureter from external pressure
- Hydronephrosis, left
- Congenital hypoplasia of kidney, right

## PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY This patient was explored by Dr Gephart and a large tumor mass found that involved half the stomach, a portion of the omentum and extended down to the region of the left kidney, which appeared to be entirely involved in the same mass. A biopsy of the tumor showed that it certainly was not lymphoma. It was an epithelial tumor with large vacuolated cells, somewhat suggestive of but by no means typical of renal-cell carcinoma, it was so reported.

The patient was transferred to another hospital, where he died a few days later. The post-mortem examination, kindly made available to us by Dr John J Larkin, the pathologist, showed a scirrhous signet-ring carcinoma of the pyloric half of the stomach. A shallow ulceration was present on the anterior wall. The tumor had grown through the gastrocolic omentum to involve the colon and had metastasized extensively in the mesenteric and retroperitoneal lymph nodes. A group of these enlarged nodes surrounded the left ureter, obstructing it by pressure and so producing a hydronephrosis. The right kidney was very small, perhaps congenitally hypoplastic, and also showed hydronephrosis. The right ureter was dilated.

## CASE 34172

## PRESENTATION OF CASE

A forty-seven-year-old woman entered the hospital complaining of pain in the left leg.

She was well until one year prior to admission, when she developed pains in the neck and back, had a gradual loss of energy, easy fatigability and an increased appetite, and had frequent loose bowel movements associated with an urgent gastrocolic reflex. There was slight exaggeration of all these

symptoms in more recent months. Six months before entry she had a barium enema, which was said to have been negative. Two weeks prior to admission the patient had several short chills and ran a slight fever. Five days prior to admission she developed discomfort in the left calf, which persisted until entry. She also had some transient pain in the right leg and during that time ran a temperature of 101°F. Upon entry she was unable to walk because of severe pain in the left calf. She gave no history of hemoptysis, nausea, vomiting or tarry stools.

Physical examination revealed a very obese woman, weighing 230 pounds. There was moderate tenderness in the left leg, extending from the ankle to 8 cm above the knee. The left calf was swollen from 1 to 2.5 cm more than the right calf. There was a positive Homans's sign in the left leg, and there were distended veins over the dorsum of the left foot. The rest of the physical examination was essentially negative.

The temperature was 99.5°F, the pulse 95, and the respirations 18. The blood pressure was 145 systolic, 90 diastolic.

Examination of the blood disclosed a hemoglobin of 13 gm and a white-cell count of 10,700, with 82 per cent neutrophils. The urine was normal. The sedimentation rate was 38 mm in one hour. The prothrombin time was 24 seconds (control, 17 seconds).

The patient was immediately started on a course of anticoagulant therapy, beginning first with heparin and then changing to dicumarol. A chest film was interpreted as negative for previous pulmonary infarcts. The fever continued, the temperature spiking to 101°F in the next few days. On the second hospital day a sharp pain developed in the left lower anterior portion of the chest, with radiation to the shoulder. A friction rub developed over this area in the chest. The prothrombin time after anticoagulant therapy was elevated to 50 seconds. The stools showed a ++++ guaiac reaction. On the seventh hospital day the patient again developed severe pain in the right calf and showed a positive Homans's sign on that side. On the ninth day a bilateral superficial femoral-vein ligation was done under local anesthesia. No thrombi were seen in the vessels. A chest film now showed linear shadows of increased density in the left costophrenic angle and possibly a small amount of fluid. The patient was placed on penicillin because of the development of a cough, with the production of a large amount of mucoid white sputum, and also the presence of rales at both lung bases. Four weeks after admission there was an exacerbation of an acute phlebitis in the left leg. The leg was painful and swollen and was about 10 cm greater in circumference than the right leg at the popliteal space. These symptoms developed under dicumarol, which

was therefore discontinued and heparin instituted. The white-cell count had risen to 23,400, with 88 per cent neutrophils. Another x-ray film of the chest showed that the left costophrenic shadow had become more linear, and there was also a small area of increased density in the posterior portion of the right lower lobe. In the fifth week pain again developed in the anterior portion of the chest, and a slight, but unmistakable, jaundice appeared. The serum albumin was found to be 2.7 gm per 100 cc, and the alkaline phosphatase was normal. The cephalin-flocculation test was ++++. Much bile was present in all the stools, many of which also showed a ++++ guaiac reaction. The van den Bergh test was 2/3 to 3/3 mg per 100 cc.

An additional history revealed that one month before entry a sharp pain had developed in the right upper quadrant, associated with anorexia, heart burn and a sensation of epigastric pressure. During that period the patient had lost approximately 14 pounds. In the seventh hospital week epigastric tenderness appeared, and a questionable mass was palpable over the area of maximal tenderness, in the left portion of the epigastrium. Bile continued to be present in the urine and the stools. The total protein was 4.2 gm per 100 cc, and the van den Bergh was 15/5 to 21/2 mg per 100 cc. The mass in the epigastrium was thought to have enlarged, but because of the marked obesity of the patient it could not be well outlined. Throughout the latter part of the patient's course the legs had become markedly swollen and edematous. She weighed 270 pounds terminally, and the edema had extended well up into the back. On the sixtieth hospital day, the patient became restless and hyperexcitable, the respirations slowed, and she died.

#### DIFFERENTIAL DIAGNOSIS

DR. REED A. HARWOOD: May we see the x-ray films?

DR. STANLEY M. WYMAN: This is the film taken on admission. It shows no definite evidence of intrinsic pulmonary disease. The right leaf of the diaphragm is higher than the left—higher than one would expect. The heart shadow is not unusual for a patient of this type. The second set of films, taken ten days later, shows the right leaf of the diaphragm even higher. The films were taken in the supine position, however. There is some indefinite density in the left costophrenic angle, and I believe that there is some fluid in the left pleural cavity. In the lateral film there is a suggestion that the right cavity also has a small amount of fluid in the posterior costophrenic sinus. Eight days later the film still shows indefinite linear density in the left costophrenic angle. It has become smaller, however, and there is some linear density in the right middle lung field. It seems to lie in the base of the right upper lobe anteriorly, close to the chest wall. There is a suggestion of an indefinite

round shadow posteriorly in one of the costophrenic sinuses—I believe the right. The next examination still shows density in the anterior base of the right upper lobe and the round density in the base probably of the right lower lobe. There is still fluid in the left pleural cavity and possibly in the right. The final film taken one month after this examination shows the right leaf of the diaphragm to have been elevated, considerably more so than on the previous examination. It is the only available film taken at that time. It makes one wonder about something going on beneath the diaphragm.

DR. HARWOOD: Would you say that the x-ray films are consistent with small pulmonary infarcts?

DR. WYMAN: They are consistent with multiple infarcts at the base of the right upper lobe and possibly of the left lower lobe.

DR. HARWOOD: The mention of jaundice is the first intimation that there was anything else present in this patient besides thrombophlebitis and multiple small pulmonary infarcts.

I do not get a very clear picture of what the illness was like after the appearance of jaundice. Obviously, she must have been very sick. Was that last film taken with a portable machine?

DR. WYMAN: Yes, it is a film taken at the bedside about seven weeks after the initial films.

DR. HARWOOD: The patient was probably too sick to have intensive studies such as a gastrointestinal series. There must be something in the record that would give additional information. Perhaps in summarizing the history some of the negative data were not included.

DR. MYLES P. BAKER: The alkaline phosphatase was elevated quite significantly at the first determination when she was mildly jaundiced, the figure was 14 or 17 units per 100 cc. The cephalin-flocculation test was not +++ on the first observation, it was either + or ++, and I believe that the thymol-turbidity tests were negative at first. Perhaps that is of some importance. It is true that the patient was too sick for further x-ray studies. During the period of increasing jaundice she was entirely aware of what was going on and doing her best to meet the doctors' requests, taking carbohydrates and so forth, and never presented the picture of a person in severe liver failure.

DR. HARWOOD: Was she conscious to the last day?

DR. BAKER: Yes.

DR. HARWOOD: This is one of those interesting cases in which the patient comes in for one complaint, and then, under observation, much more serious disease develops from which the patient dies. I tried, for a short while, to connect the complications with the initial complaints and wondered if she could possibly have had thrombophlebitis of the vena cava. I know very little about this condition, but I think that, if she had had a thrombosis of the vena cava that propagated beyond the entrance of the renal veins, she would not have survived such

an insult for more than a few days, so I ruled that out. Then there was the possibility of a thrombosis of the portal vein. The standard textbooks have very little to say about this, but they speak of the classic symptoms of hematemesis, ascites and severe upper abdominal pain — not a word about jaundice. I suppose that it could cause jaundice, but the information we have does not suggest portal thrombosis. For one thing, we do not know whether she had ascites. Perhaps Dr. Baker can give a little help on that. I think the weight gain of 40 pounds is rather sensational in a person who had such a serious disease, and I suspect that she had ascites as well as massive edema.

**DR. BAKER:** The patient had such marked edema over the back, loin and flank that it seemed as if she must have ascites, but the percussion note was resonant well over into the side of the abdomen, and one would have to say that the physical signs were not those of ascites, although it was suspected and some observers thought that it was present.

**DR. HARWOOD:** I am going to guess that she had ascites, but usually in portal thrombosis, the ascites develops rapidly, the taps very often are bloody, and the acute disturbance ordinarily leads quickly to death.

We have to admit that this patient had something wrong with the liver. The evidence of that is the low serum protein found in the fifth week of hospitalization, the positive cephalin-flocculation test and the rising serum bilirubin in the absence of obvious biliary obstruction. The question is, What was the matter with the liver? Did she have cirrhosis of the liver? That is one possibility, with polygonal-cell failure as a cause of the increasing jaundice and death. Dr. Baker has said that she did not present the picture of liver failure. One would expect a different type of death, perhaps a much deeper jaundice, and unconsciousness for several days before death. It seems to me that this diagnosis has been excluded.

Could the patient have had a partial obstruction of the common bile duct, as by stone, or a tumor in the region of the ampulla or in the head of the pancreas? Again, I think not, because at no time did she have clay-colored stools. She could not have developed this degree of obstructive jaundice without clay-colored stools. Obstruction of the common duct from any cause thus seems ruled out.

What are the other possibilities? I suppose that metastatic disease is fairly likely. To go back over

the record, "she developed pain in the neck and back, had a gradual loss of energy, easy fatigability and an increased appetite, and had frequent loose bowel movements associated with an urgent gastrocolic reflex," which suggest to me the possibility of some lesion of the upper gastrointestinal tract, or possibly a lesion in the pancreas.

The onset of carcinoma of the pancreas is apt to be insidious. The history does not quite fit that picture. Pancreatic carcinoma can metastasize to the liver, and I suppose it is possible for a situation to develop in which the metastases are largely in the left lobe, pressing on some of the larger bile ducts of the left lobe, whereas those of the right lobe, being uninvolved, permit the passage of bile.

One thinks of carcinoma of the stomach. Again, it does not fit the picture of the complaints that this woman had for a year before admission. The only thing that might fit is the one symptom of the presence of blood in the stool. She had it nearly every time the stool was examined. A carcinoma of the stomach or possibly somewhere else in the gastrointestinal tract might be the explanation of blood in the stools, and metastases to the liver might be the explanation of the jaundice. I have ruled out carcinoma of the large bowel because of the negative barium enema.

I should mention one final possibility, or rather, still another possibility, because there can be no "final" possibility in a case like this — that is, carcinoma of the gall bladder, the common duct or the ampulla. In all these cases jaundice is an early symptom, and it is usually complete. I think these diagnoses have been excluded because there was bile in the stools.

I have not mentioned primary carcinoma of the liver. This condition is most often found as a complication of cirrhosis of the liver. There is some evidence that this patient had cirrhosis, and it is possible that a primary tumor of the liver was also present. Such a diagnosis does not explain the blood in the stools, but this finding could be explained either by the elevated prothrombin time or by portal hypertension.

Although I am far from sure what this woman had, I am going to make diagnoses of cirrhosis of the liver, with a primary carcinoma of the liver, mostly involving the left lobe, thrombophlebitis of the veins of the lower extremities, possibly of the iliac veins, and multiple pulmonary emboli. I am

going to add a second choice—a carcinoma of the pancreas with metastases to the liver

A PHYSICIAN What is the possibility of liver abscess? The diaphragm was elevated. Perhaps there was some fluid there.

DR HARWOOD I meant to ask about the chart, but I am sure that Dr Baker would have told me if she had had a high temperature.

DR BAKER During the period of active phlebitis, the first week, she had a persistent fever, which subsided later.

DR MAURICE FREMONT-SMITH I want to say a few words about this patient, because I was in charge of her health for ten years up to the time of the last illness, including the beginning of it. Looking back, I realize that something happened that we always try to prevent. I cannot see any way now that it could have been prevented. She was a very high-strung woman, who had a tendency to diarrhea. When I first saw her, ten years ago, she had alternating periods of diarrhea and constipation. This continued off and on during the ten years that I took care of her. The diarrhea was affected by the environment. It stopped entirely after any problem that was puzzling her cleared up. Two years before admission to this hospital I did a rectal examination, and a little material being on the end of the glove, I smeared it on a slide, as I always do, and did a guaiac test, which was +++ Two more specimens of stool were examined, and one was faintly positive and the next negative. On the basis of this blood I insisted that she have a proctoscopy and a barium enema. The proctoscopy was done by Dr Donaldson, who was able to go the full distance of the proctoscope. The mucosa was normal. No injection, ulceration or tumors were seen, except some small hemorrhoids, which were thought sufficiently bulbous and engorged to account for the bleeding. That was approximately a year before entry. Four months later the patient again had a positive guaiac test, and I wrote to her at that time "The chances, of course, are very great that there is nothing wrong except the hemorrhoids. On the other hand, we dare not make this assumption. You should have a barium enema and proctoscopy and so forth." At that time the hemoglobin was normal. Barium enema, a month later, was, as stated in the record, absolutely normal, the colon filling rapidly without constant defects or diverticula.

DR BAKER The picture of this woman's last illness, as far as the jaundice is concerned, was that

she was gradually developing extrahepatic obstruction, judging from the laboratory tests. She had had phlebitis in both legs, and we could not really study her adequately. There was a gradual increase in the evidence of liver-cell damage. We wondered at first about the possibility of common-duct stone, recognizing the impossibility of surgery in the presence of the illness unless faced with absolute necessity. The appearance of tenderness in the epigastrium was important. The epigastric mass became more and more obvious, and was not only tender but also the site of persistent pain. Shortly before she died it became obvious that the liver was huge.

DR HARWOOD In view of the information that Dr Fremont-Smith has added, may I change my diagnosis?

DR TRACY B MALLORY Certainly.

DR HARWOOD I shall put carcinoma of the upper gastrointestinal tract—let us say of the stomach with metastases to the liver—as my first choice, and keep carcinoma of the pancreas as my second choice. Hepatoma now seems very unlikely.

DR EDWARD HAMLIN, JR. The only thing that Dr Harwood has not dwelt on is the rather extraordinary lack of efficacy of the treatment for phlebitis. The patient had adequate therapy by both anticoagulins and despite that developed more phlebitis. The veins were tied off at a time when neither vein showed thrombosis above the level of ligation. One would ordinarily assume that the phlebitis at least would not jump the gap. Despite adequate therapy with dicumarol, the lesion went on and both iliac veins became thrombosed. That is unusual and of some importance.

DR HARWOOD Suggesting a metastatic nodule pressing on the vena cava?

DR HAMLIN Suggesting some deficiency somewhere.

#### CLINICAL DIAGNOSES

Carcinoma of liver, metastatic, primary source undetermined, probably pancreas  
Iliofemoral phlebothrombosis  
Pulmonary infarcts

#### DR HARWOOD'S DIAGNOSES

Carcinoma of stomach  
Metastatic carcinoma of liver  
Thrombophlebitis  
Multiple pulmonary infarctions

## ANATOMICAL DIAGNOSES

*Adenocarcinoma of ascending colon, with metastases to liver*

*Thrombophlebitis of both femoral and iliac veins and of inferior vena cava*

Pulmonary emboli, multiple, with pulmonary infarction

Dependent edema

Ascites, slight

## PATHOLOGICAL DISCUSSION

DR MALLORY Post-mortem examination showed an enormous liver, weighing over 5 kg, completely replaced by metastatic carcinoma. Only very tiny patches of normal liver tissue could be found anywhere within the organ. The primary site of the tumor was in the ascending colon 3 cm above the ileocecal valve — a region where x-ray examination with a barium enema is ordinarily very accurate.

Both common iliac veins, as Dr Harwood predicted, were thrombosed, and thrombus also extended up the vena cava, practically to the mouths of the renal veins. The lower portion of the thrombus in the vena cava showed a considerable degree of organization, indicating that it had been present for a considerable time. There was massive edema of both legs and of the sacral and back regions, undoubtedly primarily dependent on thrombosis of the vena cava. The patient was perfectly vulnerable to vena-cava obstruction because she had had a previous hysterectomy, with consequent destruction of both ovarian veins, which are two of the most important sources of collateral circulation for obstruction of the inferior vena cava. She had had multiple pulmonary emboli, and these had produced

a series of infarcts in the lung some of which were old and completely scarred, and others in all stages of more recent development down to one quite fresh one that must have occurred only a few days before death.

DR FREMONT-SMITH Was there any ascites?

DR MALLORY There was only 800 cc of fluid, which would not have been detectable in this particular patient on physical examination. Whether the extreme enlargement of the liver was sufficient to produce functional obstruction of the vena cava and thereby increase the tendency to thrombosis, I cannot answer with certainty.

DR F DENNETTE ADAMS The tumor itself might account for it.

DR MALLORY There were no actual tumor nodules that could be seen pressing on or obstructing the vena cava.

DR ADAMS I meant that the presence of cancer anywhere in the body more or less tends to facilitate thrombosis.

DR FREMONT-SMITH How large was the tumor in the cecum?

DR MALLORY A small annular lesion at the time of autopsy.

DR HAMLIN To go back to the phlebitis. Despite the fact that the prothrombin time without therapy was elevated and despite the further elevation produced by anticoagulants she went on to thrombosis. I am not aware of any comment in the literature that the presence of an overwhelming malignant lesion will produce phlebitis, but it is certainly the impression of people like Dr Allen that such lesions cause phlebitis. The very fact that this rather paradoxical situation took place indicates that an overwhelming malignant tumor was present.

## BRITISH MEDICINE AT THE CROSSROADS

THE National Health Service Bill of Great Britain was enacted by Parliament on November 6, 1946, and unless changed by Parliament will become effective on July 5, 1948. It will take British medicine a long mile down the left-hand road—in company with the rest of Britain's institutions.

According to this act the Minister of Health is made responsible for setting up a service that is intended to improve the "physical and mental health of the people of England and Wales, and the prevention, diagnosis, and treatment of illness, and for that purpose to provide or secure the effective provision of services. These services will be rendered free of direct cost to the recipients.

The Ministry of Health is also charged with indirect responsibility for organizing and maintain-

ing "General Medical Services, Health Centers, and all other health services, such as Maternal and Infant Welfare, Home Nursing and Midwifery." All doctors may join the new services, none are required to. Remuneration is settled by regulation and is made up of a "fixed part-salary" and a capitation fee, the latter decreasing as the number of a doctor's patients rises. The sale of practices, long an accepted transaction in Great Britain, is prohibited.

The opponents of the act point out that it means centralization of authority in the office of the Minister of Health (and England has had five Ministers of Health in seven years), intervention of a social worker between doctor and patient, the promise to its beneficiaries of complete medical, dental and nursing services without obvious cost, and the creation of a great lay bureaucracy to administer the program. It means also an estimated cost of at least \$1,800,000,000 during 1948 and, inferentially, the ultimate enslavement of all physicians, dentists and nurses into salaried government positions.

A year ago the British Medical Association, as conservative as cold roast beef was once considered to be, held a plebiscite on the act and voted 23,110 against it and 18,972 in favor, with 14,589 members abstaining. On January 31, 1948, a second plebiscite was held that resulted in a vote of 40,814 against the act, or 89.5 per cent of those voting, and 4,735 in favor of it. Another year of socialism, combined with an unfortunately dictatorial attitude on the part of Aneurin Bevan, the present minister of health, has served to crystallize the opinion of British doctors.

It is difficult to know how much of this stiffened resistance is due to an awakened appreciation on the part of the British Medical Association of what the profession stands to lose when the act goes into effect, and how much it may be the result of Mr. Bevan's apparently unco-operative and dictatorial attitude. From the debates that have taken place on the act one is forced to the conclusion that Mr. Bevan's methods have been coercive and his attitude impolitic even to the point where his judgment seems at times to be under the domination of his emotions. Win, lose or draw in this contest, it would seem that the medical profession of Great

I am not aware of any comment in the literature that the presence of an overwhelming malignant lesion will produce phlebitis, but it is certainly the impression of people like Dr Allen that such lesions cause phlebitis. The very fact that this rather paradoxical situation took place indicates that an overwhelming malignant tumor was present.

policies of the Commonwealth' On December 3, 1947, a report was made signed by R H Lee, G W Dean, F C Harrington and J D Rivest of the General Court and H D Chadwick, M D, C M Hilliard and L J Smith, M D Dr C F Wilmsky served as consultant, and Drs Carl E Buck and Robert E Rothermel, of the American Public Health Association, were technical advisers Owing to a very short working period and limited budget the commission confined its studies to a few important problems and has asked that it be revived to permit further study A major set of recommendations involves simplifying the pattern of the Massachusetts Department of Public Health to give the Commissioner a modern working organization

The local health units of Massachusetts are the subject of other important recommendations A quotation from the very interesting report of the commission outlines its opinion on local health administration as follows

Massachusetts may take pride in the fact that on the record of its vital statistics as relating to infant mortality maternal mortality the absence of smallpox from the Commonwealth the low typhoid fever morbidity the provision it makes for hospitalizing tuberculosis patients and many other responsibilities it compares favorably with other parts of the country However the Commission is not satisfied with just doing a good job — it wants to see the best possible public health program continue to evolve in Massachusetts That it is not accomplishing all that it might is reflected in tables presented in the appendix in Dr Buck's report which reveals that in the five year period 1941-1945, there were 1,583 deaths from what he calls preventable causes and over 70,000 from controllable causes On the basis that preventable diseases are preventable and that those listed as controllable could be reduced by one half to one third he estimates that 6,126 lives could be saved annually representing if we choose to evaluate lives in terms of \$5,000 each an annual saving of \$30,630,000

The expenditure of a relatively small amount of money for the development of local health departments would to a large extent bring about substantial savings of both lives and money Experiences in Massachusetts and throughout the nation have convinced the Commission that a definite program for the formation of local health departments must be developed including legislation providing for their formation their financial support and their establishment at as early a date as practicable.

The commission has not yet recommended the detailed pattern best adapted for development of local health services in the Commonwealth It has stated, however, that the greatest needs in the formation of local health departments are the following

a sound, state-wide program of education and health information to bring about universal understanding of the need and value of full-time health services, a plan for state financial assistance in the maintenance of full-time local health departments, and an adequate staff of full-time, well trained public-health personnel with good salaries provided to attract such people

It is essential that these important suggestions lead to definite action A very specific recommendation is that the Governor immediately appoint a strong committee to begin the proposed program of health education

The plan for developing full-time local health services for the whole population is, of course, in accord with principles endorsed by the American Medical Association as one deserving the full support of state and local medical societies

### THE GIRLS' TERM

A BILL recently introduced in the New York State Legislature will, if passed, revolutionize and vastly improve the court method of handling cases involving wayward girls, according to a release of the New York Tuberculosis and Health Association Any attempt at solving this problem, which is acute in all metropolitan areas, will be watched with interest and hope The proposed bill has the support of many welfare agencies

The bill has resulted from the obvious need of a specialized court for the girl of sixteen to twenty-one years, as demonstrated by ten years' experience with New York City's Wayward Minor Court for Girls This experience has led students of the problem to believe that not minor repairs but a thorough overhauling of present laws is necessary

A new court to be known as The Girls' Term is proposed The proceedings of this court will be interpreted as civil in character and outside the Code of Criminal Procedure or the Penal Law The court will have the power to order that action be taken to correct a situation within its purview, but the penalty for noncompliance will be a ruling of contempt rather than prosecution under a penal statute and in a different court

Under existing law, parents, who often cause the conditions that are responsible for a girl's way-

wardness, must appear as complainants against their daughter. A situation is thus created that contributes to parent-child hostility rather than to an improvement of these relations. Under the new bill action could be taken on a petition by any responsible person, after the court had made a preliminary investigation. Informal hearings could then be held without the formality of placing girls below eighteen years of age under oath.

Present law requires a police officer who observes a girl conducting herself in a wayward manner to obtain a warrant for her arrest. The proposed law would permit her to be placed in protective custody. Most important of all, the new law, if enacted, provides that an "order of disposition" only need be rendered, and the presiding justice is permitted wide discretion in fixing the terms of such an order.

Gradually, we are breaking away from a puritanical concept of criminality. We are learning that justice may be served better by a helping hand upward than a push with the foot downward. Wayward behavior on the part of any of us may be an expression of insecurity, it should not be treated as a sign of viciousness.

## OBITUARY

### REID HUNT

1870-1948

Reid Hunt, emeritus professor of pharmacology at Harvard Medical School, died on March 7, 1948, after a long illness. He was the last of the great group of medical scientists that established Boston as an international medical center in the first three decades of the twentieth century.

Dr. Hunt was born in Martinsville, Ohio, on April 20, 1870. He received his education there and at Wilmington College and Ohio University, later receiving his baccalaureate degree from Johns Hopkins in 1891. In 1892 he worked with Binz and Nussbaum in Germany, he then returned to Johns Hopkins, where he received his doctorate in physiology in 1896, simultaneously acquiring his degree in medicine from the University of Maryland School of Medicine. From 1896 to 1898 he served as tutor in physiology at Columbia University College of Physicians and Surgeons. The next two years were spent in Egypt on biologic researches. He then returned to Hopkins and began his work in pharmacology under Abel. From 1902 to 1904 he worked in Ehrlich's laboratory in Frankfurt. In 1904 he returned to take the position of chief of

the Pharmacological Division in the Hygienic Laboratory of the United States Public Health Service. Here he remained until he came to the Harvard Medical School in 1913 as professor of pharmacology, becoming emeritus professor in 1936.

Few scientists have left as many permanent contributions. His work was planned with meticulous care and carried out with superb operative technique. As a result of this careful attention to all phases of the problem he was investigating his papers are conclusive and complete. His first paper on the accelerator nerves of the heart is a classic. He demonstrated the balance between the parasympathetic and sympathetic nerves in this organ and explained the mechanism of the nervous control of the heart beat. His second major contribution was a study of the toxicity of methyl and ethyl alcohols. Undertaken long before the prohibition era these studies were the basis of important medicolegal decisions during that unhappy period. To the other important landmarks in pharmacology and physiology that were attained through his researches may be added his work on arsphenamine in which he devised a practical method for predicting the toxicity of samples of this drug and enabled the Commonwealth to distribute it without fear of the dreaded reactions that were common in earlier samples.

In addition to his primary interest in the science of pharmacology he had ever in mind the application of scientific principles to the use of drugs in the clinic. He steadily insisted that physicians prescribe drugs by their official or semiofficial names in preference to the use of proprietary names. In this campaign he led the Council on Pharmacy and Chemistry of the American Medical Association and did much to co-ordinate its reports in *New and Nonofficial Remedies* with the decennial revisions of the *United States Pharmacopoeia*. He was president of the Pharmacopoeial Convention from 1920 to 1930. As a member of the editorial board of the *Journal* he gave freely of his time and sage advice. From his arrival in Boston he was a familiar figure at all the local medical and scientific meetings, and his encyclopedic knowledge of the literature enabled him to contribute much to the success of the discussions that are such a valuable part of such gatherings.

Personally Dr. Hunt was shy and retiring. He was at his best in conversation with individuals and small groups. He had the faculty of thinking through any problem with such thoroughness that when he spoke in council there was nothing left to be said, because of this faculty his advice was widely sought, and he occupied consulting posts of great variety. Through his conversation there ran a vein of humor and kindness and a complete absence of bitterness, though his scientific standards were uncompromising. He had a delightful sense of the ridiculous, his conversation abounded in anecdotes of the great and near-great. He especially loved to

tell of Ehrlich and his absent-mindedness. Above all he possessed great charm and captivated all who had the privilege of being with him intimately.

Many honors came to Dr. Hunt membership in learned societies here and abroad, including the National Academy of Sciences, the American Academy of Arts and Sciences, the Association of American Physicians, the Leopold-Carol Akademie, the Deutsche Pharmakologie Gesellschaft, the American Physiological Society and the American Society for Pharmacology and Experimental Therapeutics. Of the last he was the first secretary and the third president. He was chairman of the Northeastern Section of the American Chemical Society and consultant to the Massachusetts Board of Health and to the Chemical Warfare Service of the United States Army. He was a member of the Drug Standardization Committee of the League of Nations and chairman of the Council on Pharmacy and Chemistry of the American Medical Association.

Dr. Hunt's death removes one of the very last of the group of scientists that raised the United States to a position of eminence in the field of physiology. He in common with his colleagues had a broad biological background to bring to the medical sciences. This gave their researches a fundamental quality that transcended the limits of medical practice. In addition to this background Hunt brought to every discussion his encyclopedic knowledge of the literature including not only his own field but also those of general biology, chemistry and even clinical medicine. The memory he leaves in the hearts of those who knew him intimately is sweet, and his scientific contributions will be a lasting monument.

## MASSACHUSETTS MEDICAL SOCIETY

### DEATH

Born — Melville G. Boyd M.D. of Dalton died recently. He was in his fifth year.

Dr. Boyd received his degree from Queen's University Faculty of Medicine Kingston Ontario in 1929.

## MISCELLANY

### VETERANS ADMINISTRATION RESIDENCY TRAINING IN NEUROPSYCHIATRY

A limited number of openings are available for July 1, 1948, appointment to the Veterans Administration residency training program in neuropsychiatry. This program is under the jurisdiction of the deans of the Boston medical schools (Harvard, Tufts and Boston University). Training in this program which may be from one to three years is given at Cushing Veterans Administration Hospital, Framingham, Massachusetts; Bedford Veterans Administration Hospital, Bedford, Massachusetts; The Mental Hygiene Clinic of Boston Regional Office of Veterans Administration, Boston; Veterans Administration Hospital, West Roxbury, Massachusetts; and Veterans Administration Hospital, White River Junction, Vermont.

Emphasis to the entire program is on psychiatry with dynamic orientation and includes closed ward, open ward, outpatient and child psychiatry and ophthalmology.

Further information may be obtained from the Chief Neuropsychiatrist, Veterans Administration Branch Office No. 1, 55 Tremont Street, Boston 8, Massachusetts.

## CORRESPONDENCE

### A TIMELY WARNING

To the Editor: The trustees of the Tewksbury State Hospital and Infirmary are much disturbed at the number of patients sent to the Hospital who live only twenty-four or forty-eight hours after entrance. We realize fully that it is difficult to evaluate the condition of many patients suffering from a long chronic disease, and also that removal to the hospital may be justifiable because of economic conditions, even though the patient's condition is serious.

We are writing this letter to call the attention of physicians to the General Laws of the Commonwealth Chapter 122, Sections 16 and 17 which state that no town officer shall remove a sick person to the hospital unless there is reasonable cause to believe that such removal will not injure or endanger his health and in case of doubt shall obtain a certificate of a competent physician that he has examined the patient and that he can be removed without injury to his health.

Recently a decision was handed down by the Massachusetts Supreme Court affirming a judgment of \$7000 against a physician for sending to the hospital, some eighty miles by automobile, a patient who died within twenty-four hours.

Last month a patient was sent from a town some twenty miles from Tewksbury and was found dead on arrival.

We hope that physicians sending patients to Tewksbury will in the future be more careful in their examination of such patients.

ROBERT L. DeNORMANDIE, M.D., Chairman  
Board of Trustees

Commonwealth of Massachusetts  
Department of Public Welfare  
Tewksbury State Hospital and Infirmary

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*Studies from The Rockefeller Institute for Medical Research.* Reprints Volume 134, 4<sup>th</sup> paper 605 pp. New York: The Rockefeller Institute for Medical Research, 1947. \$2.00.

This volume of studies brings together in one volume the contributions of members of the staff of the Rockefeller Institute scattered throughout many periodicals. The period covered is approximately the first half of 1947.

*Health Instruction Yearbook 1947.* Compiled by Oliver E. Byrd, Ed. D. M.D., professor of health education and director, Department of Hygiene School of Education, Stanford University. With a foreword by Clair E. Turner, Sc.D., Dr. P.H. National Foundation for Infantile Paralysis. 8<sup>th</sup> cloth 325 pp. Stanford, California: Stanford University Press, 1947. \$3.00.

This basic reference serial, now in its fifth year, abstracts the recent literature on public health. For this volume 323 articles were selected from a total of 1672 read by the editor in 95 different periodicals. The material is divided into twenty-one subject fields. A bibliography of the selected articles is appended to the text. An alphabetical list of sources and a good index conclude the volume. The type, printing and paper are excellent. The volume is recommended for all medical and general libraries and should prove valuable to all persons interested in public health.

*Congenital Malformations: A study of parental characteristics with special reference to the reproductive process.* By Douglas P. Murphy, M.D., assistant professor of obstetrics and gynecology and research associate in the Gynecological Institute of Gynecologic Research, University of Pennsylvania. Second edition. 8<sup>th</sup> cloth 127 pp. with 65 illustrations. Philadelphia: J. B. Lippincott Company, 1947. \$5.00.

This second edition of a monograph first published in 1940 has been expanded by the addition of a second part on the environmental basis of congenital malformations, comprising a study of a series of cases of maternal pelvic irra-

diation and maternal rubella. The first part, from the first edition, discusses the genetic basis in its various aspects. The author concludes from his studies that human congenital defects usually arise from factors present in the male or female germ cells prior to fertilization, and that after fertilization has taken place, they may be produced either by the action of therapeutic amounts of maternal pelvic radium or roentgen irradiation or by a maternal attack of rubella during pregnancy. Likewise, there is no clinical evidence that irradiation of the human egg cell, prior to fertilization, influences the health or development of the resulting infant, and there is only suggestive evidence that an attack of maternal rubella, prior to conception, influences the development of any following offspring. The existing evidence warrants two statements: when a congenital malformation has a genetic basis, there is a greatly increased chance that subsequent brothers or sisters will also be malformed, and when a congenital defect is due to factors that are not genetic in origin, offspring conceived subsequently should be congenitally malformed only with the same frequency as that commonly observed in the population at large. A selected bibliography and index conclude the volume. The publishing is good. This statistical study should be in all reference medical libraries.

*A Text-Book of Pathology. An introduction to medicine.* By William Boyd, M.D., Dipl. Psych., M.R.C.P. Edin., F.R.C.P. Lond., LL.D. Sask., M.D. Oslo, F.R.S.C., professor of pathology and bacteriology of the University of Toronto. Fifth edition, thoroughly revised 8°, cloth, 1049 pp., with 500 illustrations and 30 colored plates. Philadelphia: Lea and Febiger, 1947. \$10.00.

This standard textbook has been revised to date, and much new material incorporated in the text. Sections have been added on stasis, botryomycosis, Tsutsugamushi fever, dermatofibroma, sclerosing hemangioma, hypertensive heart disease, cardiac infarction without coronary occlusion, temporal arteritis, mucosal respiratory syndrome, Löfner's pneumonia, giant-cell pneumonia, chronic disseminated tuberculosis, aspergillosis, intestinal lipodystrophy, alloxan diabetes, renal anoxia, malakoplakia of the bladder, interstitial-cell tumor of the testis, primary splenic neutropenia, pyridoxin-deficiency anemia, the anemia of infections, fibrous dysplasia of bone, hyperostosis frontalis interna, odontogenic tumors, the relation of vitamin C to bone repair and other subjects. The sections on carcinogenesis in relation to enzymes and viruses, silicosis and anthracosis, neurosis and cirrhosis of the liver, Cushing's syndrome, the Rh factor in congenital hemolytic disease, ankylosing spondylitis and Volkmann's contracture have been rewritten. The chapter on allergy, omitted from the previous edition, has been rewritten and restored in this edition. The volume is well published and should be in all medical-reference collections.

## NOTICES

### ANNOUNCEMENTS

Dr. Charles Isenstein announces the removal of his office to 1587 Massachusetts Avenue, Cambridge, for the practice of ophthalmology.

Dr. David E. Kopans announces the removal of his office to 475 Commonwealth Avenue, Boston, for the practice of obstetrics and gynecology.

Dr. Edward T. Moses announces the removal of his office to 543A Highland Avenue, Malden (48).

### NEW ENGLAND OBSTETRICAL AND GYNECOLOGICAL SOCIETY

The spring meeting of the New England Obstetrical and Gynecological Society will be held at Hartford, Connecticut, on Wednesday, May 5, with clinics at the Hartford and St. Francis hospitals and a dinner at the Hartford Club.

### AMERICAN ORTHOPAEDIC ASSOCIATION

A meeting of the American Orthopaedic Association will be held at the Chateau Frontenac, Quebec, from June 3 to 6. This will be a joint meeting with the British Orthopaedic Association and the newly formed Canadian Orthopaedic Association.

### AMERICAN PSYCHIATRIC ASSOCIATION

The 104th annual meeting of the American Psychiatric Association will be held at the Statler Hotel, Washington, D. C., from May 17-20 (the permanent head office of the Association is at 9 Rockefeller Plaza, New York 20, New York), and not in Portland, Oregon, from May 9 to 14, as announced in the April 1 issue of the *Journal*.

### SOCIETY MEETINGS AND CONFERENCES

#### CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING THURSDAY, APRIL 29

##### FRIDAY, APRIL 30

\*9 00-10 00 a. m. Medical Experiences in Germany (March, 1948), Dr. Alexander Marble. Joseph H. Pratt Diagnostic Hospital.

\*10 00 a. m.-12 00 m. Medical Staff Rounds. Peter Bent Brigham Hospital.

##### TUESDAY, MAY 4

\*12 00 m. X-ray Conference. Margaret Jewett Hall, Mt. Auburn Hospital, Cambridge.

\*12 15-1 15 p. m. Clinicoroentgenological Conference. Peter Bent Brigham Hospital.

\*1 30-2 30 p. m. Pediatric Rounds. Burnham Memorial Hospital for Children, Massachusetts General Hospital.

##### WEDNESDAY, MAY 5

\*12 00 m. Grand Rounds and Clinicopathological Conference. (Children's Hospital) Amphitheater. Peter Bent Brigham Hospital.

\*2 00-3 00 p. m. Combined Clinic by the Medical, Surgical and Orthopedic Services. Amphitheater, Children's Hospital.

\*Open to the medical profession.

APRIL 23 and 24. American Society of Anesthesiologists, Inc. Page 582, issue of April 15.

APRIL 26. New England Heart Association. Page 582, issue of April 15.

APRIL 26-29. American Dermatological Association. Page 456, issue of March 25.

APRIL 28. Massachusetts Society for Social Hygiene. Page 582, issue of April 15.

APRIL 29-MAY 2. American Academy of Pediatrics. Page 240, issue of February 12.

APRIL 30 and MAY 1. American Gastro-Enterological Association. Page 456, issue of March 25.

MAY 1. Suffolk District Medical Society. Page 543, issue of April 8.

MAY 3. American Society for Clinical Investigation. Page 456, issue of March 25.

MAY 3 and 4. Association of American Physicians. Page 492, issue of April 1.

MAY 4. Suffolk District Medical Society. Annual Meeting. Page 582, issue of April 15.

MAY 4 and 5. Association of Military Surgeons of the United States. Page 456, issue of March 25.

MAY 5. New England Obstetrical and Gynecological Society. Notice above.

MAY 6. Suffolk Censors' Meeting. Page 344, issue of March 4.

MAY 6-8. American Association for the Study of Gonorrhea. Page xiii, issue of July 31.

MAY 11. Harvard Medical Society. Amphitheater of Building D, Harvard Medical School. 8:00 p. m.

MAY 12-14. American Association of Genito-Urinary Surgeons. Skytop Lodge, Skytop, Pennsylvania.

MAY 13. Indications for the Use of Forceps. Dr. Roy J. Heffernan, Pentucket Association of Physicians. 8:30 p. m. Haverhill.

MAY 16-22. American Board of Obstetrics and Gynecology, Inc. Page 344, issue of March 4.

MAY 16-23. International College of Surgeons. Page 136, issue of January 22.

MAY 17-19. American Ophthalmological Society. Page 492, issue of April 1.

MAY 17-20. American Urological Association. Hotel Statler, Boston.

MAY 17-20. Association for the Study of Internal Secretions. Page 492, issue of April 1.

MAY 17-20. American Psychiatric Association. Notice above.

MAY 18-22. American Association on Mental Deficiency. Copley Plaza Hotel, Boston.

MAY 20-25. American Board of Ophthalmology. Page 170, issue of January 29.

## AN EVALUATION OF CURARE IN SPASTICITY DUE TO SPINAL-CORD INJURIES\*

ROBERT A. KUHN, M.D.,† AND DONALD S. BICKERS, M.D.‡

FRAMINGHAM, MASSACHUSETTS

IN 1850 Claude Bernard<sup>1</sup> demonstrated the site of action of curare to be the neuromuscular junction. His experiments have been verified by numerous investigators, and in 1935 West<sup>2</sup> and King<sup>3</sup> clarified the mode of action and enumerated the pharmacologic properties of the drug. It was not until 1943 that Wintersteiner and Dutcher<sup>4</sup> crystallized the quaternary ammonium salt, d-tubocurarine chloride. Recent availability of this pure preparation has stimulated clinical and pharmacologic investigations.

The gross effects of curare on the normal human subject have been thoroughly investigated. The intrinsic musculature of the toes and eyes demonstrates early paresis, which successively involves the muscles of the limbs, head and neck. Inter-costal muscle relaxation is soon followed by paralysis of the diaphragm. During the early stages of curarization, the patient complains of blurring and fuzziness of vision. The eyelids droop, diplopia develops, and the jaws relax. There is weakness and heaviness of the neck muscles progressing to head drop. Further administration of the drug produces complete peripheral paralysis and, finally, respiratory arrest.<sup>5</sup> These signs and symptoms disappear in reverse order, and the rate of disappearance is dependent upon the nature of the curare preparation administered.

Although it is known that curare exerts its influence primarily at the myoneural junction, the exact mode of action remains in doubt. Eccles, Katz, and Kuffler<sup>6-10</sup> demonstrated that the end-plate potential in fully curarized muscle rises to sub-threshold levels and subsides without initiating muscle response. The size of the potential—that is, the degree of depolarization—depends in part on the concentration of the curare in the muscle. The degree of block is controllable, and certain frequencies can be suppressed. This action may well explain obliteration of various involuntary move-

ments while normal voluntary contractions continue.<sup>11</sup>

Clinically, curare has been used with value in a number of conditions necessitating muscle relaxation. Curare therapy of tetanus has met with some success,<sup>12-18</sup> and convulsions incident to shock therapy are effectively diminished.<sup>16-18</sup> However, it is in anesthesiology that this drug has achieved its maximal usefulness to date. In 1942, Griffith<sup>19</sup> reported the use of curare as an adjuvant to general anesthesia, and numerous excellent studies in succeeding years have thoroughly established its value in this field.<sup>20-25</sup>

In 1942 Denhoff and Bradley<sup>26</sup> conducted a controlled study of the effectiveness of aqueous curare in relieving the spasms of children with cerebral diplegia. They concluded that progress under physical therapy was definitely accelerated in these subjects. Muscular relaxation with maximal therapeutic dosages was maintained for a period of approximately four days. Burman,<sup>27</sup> Bennett<sup>28</sup> and Schlesinger<sup>11</sup> reported similar success in patients exhibiting spasticity and rigidity.

Recent reports have indicated that curare might offer valuable aid in the amelioration of spastic paraplegia and paraparesis.<sup>11, 29, 30</sup> Schlesinger<sup>31</sup> administered aqueous curare to 11 patients with extreme spasticity due to spinal-cord injuries and obtained excellent but transient relaxation. A suspension of d-tubocurarine chloride in a peanut-oil and white-wax mixture was prepared in an effort to retard the rate of absorption. The curare effect was found to be prolonged up to three days in some cases, and effective reduction of spasticity<sup>32</sup> was not accompanied in any case by unpleasant side reactions. The effect of the curare in oil on patients exhibiting voluntary function masked by spasm seemed more dramatic than that observed in paraplegic patients.

Severe spasm of muscle groups innervated below the level of the cord lesion is frequently a major manifestation of spinal-cord injury, whether due

\*Anatomic transection of the spinal cord (verified by exploration)

†Physiologic transection of the spinal cord

such an injury Munro<sup>32</sup> has discussed these complications in detail

Troublesome decubitus ulcers are frequently encountered in patients with cord injuries. These lesions, when present on the heels, knees or hips,

may lead to permanent contractures of tendons and joints, and neither intensive physiotherapy nor surgery is of much avail. Bladder management is difficult to achieve in these subjects, and the important task of teaching the patient to ambulate

effectively is virtually impossible. The person with spasm can be forced into braces, which can be locked in position, but he will never learn the balance that

a wheelchair life. Unfortunately, only a few patients are able to "tire" their minimal spasms with a short period of exercise or physiotherapy.

TABLE 1 (Continued)

DEGREE OF SPASM		DEGREE OF PAIN		REMARKS
BEFORE TREATMENT	AFTER TREATMENT	BEFORE TREATMENT	AFTER TREATMENT	
+++	+++	0	0	No improvement; dizziness on 9th and 13th days.
++++	+	++	+	Marked improvement; moderate relaxation and drowsiness on 3rd, 5th and 7th days.
++	+	0	0	Questionable improvement; dizziness on 5th, 9th and 21st days.
++++	++++	0	0	Spasms unabated; weakness and diplopia on 5th, 11th, 15th and 17th days.
++++	++++	0	0	Spasms unabated; no symptoms of any type.
++	++	++	++	Spasms unchanged; no symptoms.
+++	++++	+	—	Spasms worse; bitter complaints of visual blurring on 5th, 7th and 9th days.
++	++	+	+	Questionable improvement; headache on 7th and 9th days.
++++	++++	+	+	No symptoms; spasms unabated.
++++	++++	+	+	Severe spasms; nystagmus; slight dizziness on 7th day.
++++	++	++	+	Hamstrings and abdomen moderately relaxed; patient sleeps better.
++++	++++	++	++	Patient seemed suggestible; spasms unchanged.
++	++	0	0	Spasms unchanged; moderate dizziness on 7th, 9th and 11th days.
+++	+++	+++	+++	Weakness, blurring and severe dizziness through out.
+++	+++	+	+	Patient asymptomatic; spasms unchanged.
++++	++++	+	+	Fitting edema of hands and feet on 5th, 7th and 9th day; spasms unchanged.
+++	+++	+	+	Patient asymptomatic, with no change in spasms.
++	++	++	++	No symptoms; spasms unchanged.
+	++	0	0	Spasms worse, with weakness, on 7th, 17th and 19th days; dizziness on 15th day.
+++	++	0	0	Dubious improvement in spasms.
++++	++++	0	0	No changes of any nature noted.
++++	+++	0	0	Spasms generally improved; weakness on 17th and 19th days and diarrhea on 7th day.
+	+	0	0	Questionable relief of spasms; severe weakness on 17th and 19th days; syncope on 5th day.
++++	+	0	0	Spasms markedly alleviated in all components; patient sat for first time.
++++	++++	0	0	No changes of any type noted.
++++	++	0	0	Spasms moderately but definitely decreased; drowsiness on all days.
++	++	0	0	Patient asymptomatic; spasms unabated.
++	++	0	0	Spasms unchanged; but patient sleeps more; drowsiness on 7th, 9th and 11th days.
+++	+++	0	0	Spasms unabated; dizziness on 7th and 9th days.
++	++	0	0	No changes of any type noted.
++	++	0	0	Spasms unchanged; dizziness on 7th and 9th days.
++++	++++	+	+	Excitable patient; spasms unchanged; weakness on 5th, 9th and 17th days.
+	++	+	+	Spasms seemed worse; patient asymptomatic.
+++	+++	+	0	Spasms unchanged; drowsiness on all days, weakness on 3rd, 13th and 15th days.

is essential to walking. Pelvic jackknifing, asymmetry of spasms in the lower extremities and the utter unpredictability of onset militate strongly against satisfactory adjustment. The patient becomes wary, loses confidence and resigns himself to

During the past year, we have attempted to relieve spasm by a number of methods. Prostigmine and atropine administered parenterally have not been successful. Local injection of spinal nerves with procaine or related preparations provides relief of

very short duration. Anterior rhizotomy has been performed as a last resort, the extent of nerve section depending upon the problem presented by the individual patient. Effort has always been made to carry out the simplest, safest and least destructive procedure first, anterior rhizotomy being reserved for patients not benefited by prolonged trial of the less radical methods.

Transient beneficial effects were observed to follow the intramuscular injection of aqueous curare, but were nullified by incapacitating toxic symptoms. It was believed that d-tubocurarine in oil, because of its slow rate of absorption, might provide longer lasting relief of spasms without toxic side reactions. Therefore, the present study was undertaken.

### METHODS

Thirty-four patients on the Paraplegia Service were selected as spastic problems. The spasms ranged from mild muscle-group twitchings of almost subclinical importance to spasticity so marked as to prevent any form of ambulation. Levels of cord injury ranged from the fifth cervical to the tenth thoracic segment. Seventeen patients had been injured by high-explosive shell fragments, and 10 by gunshot wounds, and 7 had sustained compression fractures of one or more vertebrae. Nine men had suffered partial lesions of the cord, and 25 demonstrated clinical evidence of complete transections. In the average patient, spasms were first noted approximately six weeks after injury (Table 1).

The 34 patients were divided into two groups of 17 each, and an attempt was made to distribute them evenly according to the level of injury and severity of spasm. Patients in the first group were given 175 mg (1 cc) of d-tubocurarine in oil and wax\* intramuscularly every forty-eight hours for a total of ten doses. Those in the other group were given physiologic saline solution (1 cc) intramuscularly at similar intervals and for the same period. Two series were studied, separated by an interval of approximately two months. In the first series, 16 patients were given injections, half of them receiving the medication, and half physiologic saline solution. The second series was managed similarly with a total of 18 patients. No attempt was made to isolate those under treatment, and communication between patients of the same and different wards was unrestricted. To minimize prejudicial estimates of improvement because of previous knowledge of the medication received, neither the observer in the first series (R A K) nor that in the second (D S B) was cognizant of the distribution of controls or drug injections. The distribution remained unknown to the observer until all injections had been completed and his written report submitted. In each series, one nurse gave injections

from beginning to end of the treatment period. Patients were told only that they were receiving "medicine for spasms." Nurses and doctors were under strict injunction to guard against elaboration of this single statement. The injections were completely prepared, and the needles attached under sterile conditions in a room separate from the main ward. To promote efficiency, ten or fifteen syringes were carried in a closed container from ward to ward. A hot-water bottle covered with a sterile towel served to maintain the d-tubocurarine in liquid state. All syringes were taped to the 1-cc mark, the quantity of injectable material kept the same in each syringe, and the barrel and needle end covered by the nurse until the moment of injection into the gluteal region. The necessity for such elaborate precautions is demonstrated by reference to the case reports presented below.

Clinical observations by doctors, physiotherapists and nurses and subjective reports by the patients were accorded most weight in evaluation of the results obtained. Clinical estimates were based upon observation of the patients' ability to ambulate and maneuver between bed and wheelchair, response of spastic extremities to pinprick and other stimuli, and resistance of the extremities to passive motion. Each patient was questioned about the frequency, duration, severity and "sensitivity" of spasms during the periods between injections, and special care was taken to avoid leading remarks. Most patients volunteered detailed statements with as little prompting as the question, "How are your spasms?" or "Are you having any trouble?"

### RESULTS

Amelioration of spasms was apparently obtained in 7 of the 34 patients. Three of these patients were receiving curare, and 4 were receiving physiologic saline solution. The degree of estimated improvement varied, but the most marked "relief" occurred in 2 patients in the latter group. In none of the patients was improvement so marked as to justify continued administration of curare. Twenty-seven patients were unimproved, 14 of these having received curare, and 13 having received physiologic saline solution.

Pain was considered to be lessened in 3 patients—2 in the medication group and 1 in the control group. No changes occurred in the remaining 31 patients.

Toxic symptoms were frequent and misleading. Manifestations of such symptoms by patients in the control group were usually indistinguishable from the complaints of patients actually receiving curare and frequently led to incorrect estimates of the type of medication being administered.

The role played by suggestibility in therapy of this type of patient was clearly demonstrated. Intramuscular injection of d-tubocurarine in oil demonstrated no effects on spasticity that could not be

\*The tubocurarine was supplied by E. R. Squibb and Sons, New York City.

duplicated with intramuscular injection of physiologic saline solution

The following case reports are illustrative of the series as a whole

**CASE 1** J. S., a 21-year-old man, was wounded January 20 1945, by a .31-caliber bullet, which entered the left anterior triangle of the neck, emerging through the left posterior triangle. He sustained a compound comminuted fracture of the bodies of the fifth and sixth cervical vertebrae, with complete loss of all motor and sensory modalities below the level of the fifth cervical segment. Within 2 days he was able to flex the left leg, and 7 days after injury he began to regain some motor power in the upper extremities. Depressure sensation returned completely below the level of the second rib. Débridement was performed 9 days after injury, but no attempt was made to visualize the dura or spinal cord. The patient developed a large sacral decubitus ulcer en route to the United States but the neurologic status was gradually improving. Examination in September demonstrated patchy hypesthesia which ended at the fourth lumbar dermatome on the left and the fifth lumbar and first sacral dermatomes on the right, with complete anesthesia below those levels. Motor activity returned to the left upper extremity, the right hips were weak but contracting voluntarily, and there was fair extension and flexion of the thigh on the pelvis and the leg on the thigh in the left lower extremity. Voluntary motion was present in the right lower extremity but to a lesser extent. There was no movement of the feet or toes. Concurrently with the gradual re-establishment of voluntary motor power approximately 2½ months after injury, the patient began to notice adductor flexor muscle spasms. The involuntary movements lasted approximately 30 seconds and were set off by changes in position or by attempts at initiating motion in the lower extremities. Turning in bed particularly excited movements. Abdominal spasms became more and more frequent. Despite daily physiotherapy and prolonged treatment with prostigmine and aqueous curare, flexion contractures of hips, knees and ankles gradually developed. In June, 1946, because of the danger of ankylosis a series of orthopedic procedures was carried out, including bilateral fasciotomy of the hips, bilateral adductor-logous tenotomy, bilateral triple hemisection of the Achilles tendon and left hamstring tenotomy. The lower extremities were placed in casts split over the popliteal space, and the knee flexion was slowly reduced by wedging. At the end of 1 month both lower extremities demonstrated full range of motion but with release from the cast, strong spasms again flexed the right leg. Brace and crutch ambulation began in August, 1946 but the patient continued to be severely hampered by spasms. Attempts by the patient to inhibit flexor spasms voluntarily in the left lower extremity began to evoke strong extensor spasms.

Ten injections of 1 cc (175 mg) of d tubocurarine in oil and wax were administered in the manner described above.

There was no improvement in severity, frequency or sensitivity of spasm. Toxic symptoms of overdosage occurred throughout the entire course of treatment as evidenced by blurring of vision, diplopia, dizziness, headache and weakness. Two episodes of nausea and vomiting occurred within 1 hour of injection.

**CASE 2** F. N., a 30-year-old man was injured on June 9 1945 when the truck in which he was riding plunged off a cliff in Germany. He sustained immediate complete paralysis with a sensory and motor level at the fifth dorsal dermatome. A ray study revealed comminuted fractures of the transverse processes and bodies of the fifth and sixth dorsal vertebrae and lumbar puncture demonstrated partial block. The patient was placed in hyperextension and returned to the United States. Onset of reflex activity was noted 1 week after injury with the appearance of bilateral hallux dorsiflexion. One month later there was mild abdominal spasm, and within the following few weeks mild thigh flexion appeared. At 3 months he developed an extensor component, which appeared while he was lying on the side and back. The adductor flexor type of mass reflex increased gradually in severity, and by March 1946 the spasms were strong usually extensor in pattern and set off by almost any stimulus.

Laminectomy performed on August 14 revealed an atrophic spinal cord with cystic degeneration at the level of the fourth and fifth dorsal vertebrae. Approximately one eighth of the left posterolateral column was stated to be anatomically intact. The posterior roots of the fifth dorsal segment were severed bilaterally in an attempt to relieve the girdle pains. No change resulted except for an increase in pain at that level. Ambulation was first begun on long leg braces with a back brace in April. With the exception of the postoperative laminectomy period the patient subsequently continued to ambulate. Flexion-adduction and extension spasms markedly interfered with walking and the patient had reached a point beyond which he could not progress.

Ten injections of 1 cc (175 mg) of d tubocurarine in oil and wax were administered in the manner described above.

No improvement was observed in the severity, frequency or sensitivity of spasms. Girdle pain remained the same. The patient experienced dizziness on the 5th day of treatment and some blurring of vision on the 21st day.

**CASE 3** J. D., a 34-year-old man was wounded on November 24, 1944 by a high-explosive shell fragment, which struck him in the interscapular region, inflicting a compound comminuted fracture of the laminae and bodies of the third and fourth dorsal vertebrae. There was no loss of consciousness but immediate complete sensory and motor paralysis distal to the third thoracic dermatome. After emergency supportive treatment, débridement was done. The dura was visualized, found to be intact and stated to pulsate well but the cord was completely severed. Involuntary movements began approximately 1 month after injury. They first manifested themselves as mild flexion contractions involving the thighs, legs and feet. The strength and frequency of the spasms gradually became more pronounced and 5 months after injury lumbar abdominal and adductor components entered the flexion picture. In September 1945, extensor thrust began bilaterally and an extensor component, which lasted 20 to 30 seconds, appeared with marked fatigue. To date the patient has continued his efforts at ambulation. Adductor spasm and scissoring have been partially relieved by obturator neurectomy and adductor tenotomies and it was found necessary to perform sections of both Achilles tendons to correct plantar flexion contractures. Progress has been practically nil. Strong triple flexion spasms together with severe extensor spasms have been extremely difficult to cope with. Prolonged trial with intravenous and intramuscular curare, prostigmine and atropine did not benefit the patient and operative relief was repeatedly refused. The neurologic status and general physical condition have remained unchanged for the last ten months.

The patient was included in the control series and given ten injections of physiologic saline solution throughout the prescribed course of treatment.

On the 3rd day of treatment he thought that the extensor component of the spasm was of somewhat shorter duration than normal for him. On the 5th day the same report was given and on the 7th day he reported and demonstrated definite relaxation of flexor, extensor, abdominal and gluteal spasms. He also reported mild diarrhea on that day which he attributed erroneously to the medication being administered. He continued to report daily that the spasm was improving saying "I feel more relaxed all over" and "The spasms don't last as long and I can bend my legs with my hands without making the spasm start—I could never do that before." On the 17th day he complained of mild weakness but no other toxic symptoms. He felt definitely improved and repeatedly requested after completion of the injections that they be resumed.

**CASE 4** L. D., a 29-year-old man, fell 50 feet from a hangar roof on December 21 1945 striking a concrete floor. There was immediate complete motor and sensory loss below the level of the sixth dorsal dermatome. A ray study revealed compression fractures of the bodies of the seventh, eighth and ninth dorsal vertebrae. On the following day exploratory laminectomy demonstrated complete aortic transection of the spinal cord with a gap between the ends, at the level of the ninth dorsal vertebra. There was considerable contusion of the cord at the levels of the seventh and eighth and the posterior roots of the eighth and ninth

dorsal segments were lacerated. Involuntary movements were first noted by the patient approximately 6 months after injury. They began as fibrillary twitchings in the hamstrings and gradually spread to the abdominal and gluteal muscles. A triple-flexion pattern of moderate severity evolved, with occasional abduction spasms of the thighs. He was able to ambulate throughout the summer of 1946 on long leg braces with a back brace. For the past 2 months he has had extension spasms of both thighs on rising from a supine position. Bilateral plantar flexion is a part of this general pattern. The spasms usually last about 5 to 10 seconds, but may occur at any time and are more marked while he is sitting than when he is standing. Ambulation has been only moderately hindered by the involuntary activity. The main problem confronting this patient has been poor bladder control as an accompaniment of the general spasm picture. Tidal drainage was attempted in March, 1947, with no success. The bladder has a small capacity and requires frequent emptying, with no assurance that the patient will remain dry.

This patient was selected for the control series and given 1 cc of physiologic saline solution intramuscularly every 48 hours for the usual injection period.

There was no change on the 3rd day. On the 5th day he noticed diarrhea three or four times, but there was no change in the spasms. On the 7th day he reported definite improvement in spasm frequency and severity, but complained that along with the relaxation he became dizzy, fainted and was unconscious for a period of 2 or 3 minutes. His ambulation instructor held him erect until the period of dizziness passed, but he suffered weakness and dizziness for 5 hours after the injection on that day. On the 9th day of treatment the patient stated that he was improved in all respects, with relaxation of flexor, extensor, abdominal and back spasms. The bladder was not "firing off" so frequently. He maintained this state of improvement throughout the entire course of treatment. On the 13th day he again complained of mild weakness and dizziness. He felt quite definitely that his spasms were improved and stated that they "didn't last so long." There were quite bitter complaints about the toxic symptoms he was manifesting, and because of them he wished to discontinue the injections, but was persuaded to complete the injection course. At the termination of treatment he expressed the opinion that although the spasms had been definitely improved, the fatigue and weakness accompanying injections more than counterbalanced this improvement. Accordingly, he would "rather have the spasms."

## DISCUSSION

In an attempt to evaluate the results of any medical therapy for spasms, certain limitations and difficulties must be emphasized. No objective method of measuring the degree of spasm is entirely satisfactory. Caliper or tape measurements of the range of motion possible in the spastic limb do not yield accurate data. The unpredictable and frequently abrupt "normal" variations in intensity of spasm from hour to hour are extremely confusing. It is very unusual indeed for a patient to reproduce the identical intensity and pattern of spasticity week after week. He may volunteer the information that he has recently been much less spastic than usual, but testing will demonstrate spasms that appear to be of equal or greater severity than those noted during a day when he was, by his own estimate, "jerking all the time." If the time necessary for spasm to "tire" against a given stretch is taken as an index, the same objection holds.

Normal daily variation, which is dependent upon factors not yet explained, serves to minimize the value of such measurements. Myometrograms

demonstrating the action potentials of spasmodically contracting muscles are impractical for the same reason. Standardization preliminary to recording each measurement is extremely difficult, and it is virtually impossible to establish a base line for comparison of one patient with another. Still photographs, as might be expected, are misleading. It was, unfortunately, not possible to obtain moving pictures of the reflex activity in these men. Slow-motion-picture analysis of the reflex movements resulting from a standard stimulus should yield fairly accurate data.

The dosage schedule utilized in this series was arrived at after some deliberation. As with any drug, optimal therapeutic dosage and tolerance vary with each patient. Available studies indicate that a single effective dose will continue to manifest its effect for forty-eight to seventy-two hours<sup>11, 27-29</sup>. In administering 1 cc of d-tubocurarine in oil every forty-eight hours, we preferred to err on the side of overdosage, with the hope that toxic symptoms would not become disabling and that the majority of patients would fall within the therapeutically effective range of the drug.

It must be realized that we were dealing with patients whose injuries had placed them in a unique psychologic situation. A profound sense of inadequacy governed their daily lives. Despite a superficial rationalization encouraged by association with similarly disabled patients, there remained in these men deep feelings of inferiority and helplessness. They had been forced to the logical conclusion that their disability was in all probability a permanent one, and that they would never become normal. But such a realization did not prevent severe conflict with the hope (usually unexpressed) that some new treatment would be found or that some miracle would occur to restore their limbs. Popular articles reporting amelioration or "cures" in almost any disability, vaguely or directly related to spinal-cord injury and its sequelae, brought immediate inquiry and demand for explanation. There was fertile ground for acceptance of ideas that are medically and surgically unsound. Suggestibility was maximal, and if the desire for improvement was of sufficient strength "improvement" would result no matter what agent was employed.

The importance of suggestion is strikingly emphasized by the patients who were given physiologic saline solution (Table 1). The "toxic symptoms" demonstrated by 4 patients are easily attributable to suggestion, but alleviation of spasm, sufficiently marked to impress the observer, demonstrates the facility with which suggestion completely obviates clinical observation. It stresses the need for controlled trial of any new drug in these patients. It is evident that a striking reduction of spasm can be produced by suggestion in certain patients with proved anatomic severance of the spinal cord. The

psychogenic factors involved, and their relation to spasm, are complex and deserve further investigation.

It is apparent that in neither series were the observers able to estimate correctly the patients receiving d-tubocurarine (Table 1). Of the total of 34 patients, the type of injection administered was judged incorrectly in 16. Nine patients receiving curare were estimated to be receiving physiologic saline solution, and 7 of those receiving saline solution were judged to be in the curare group. It is therefore obvious that little or no therapeutic effect attributable to curare was observed.

Twenty of the 34 patients exhibited apparent effects of "overdosage" at one time or another, 11 of these received curare, and 9 received saline solution. Diplopia and pitting edema of the hands and feet (the latter a complication of curarization previously unreported\*) were the only two findings noted in the curare group but absent in the control group. In the remainder of patients displaying "toxic symptoms" it was impossible to differentiate the drug group from the control group. The dizziness of the patients on curare differed in no way from the dizziness suffered by those receiving saline solution. Similarly, drowsiness and weakness proved extremely difficult to evaluate. The severity of symptoms was grossly misleading. In 3 patients (M E S, J S and L D) toxic symptoms were sufficiently distressing to cause us considerable anxiety. Two of these patients were receiving curare, and 1 saline solution. Despite such manifestations, it was not necessary to administer prostigmine or to discontinue injections in any patient.

The opinions of physiotherapists and physical-therapy instructors, the change (if any) in spasms, the intelligence of the patient, his adjustment to his injury and his emotional stability were factors that influenced the decision whether or not he was receiving curare. Naturally, the degree of conviction concerning the type of medication being administered varied for each patient, and in some cases a definite opinion was difficult to formulate.

Seven patients with partial cord lesions received curare, and 2 received saline solution. The preponderance of the curare group was unintentional but fortunate, since it offered an opportunity to compare results of curare in patients with paraparesis and those with paraplegia. Three of these patients were incorrectly judged to be receiving saline solution. One patient was markedly relaxed, and 1 moderately so. In the group receiving d-tubocurarine none of the patients with complete transection of the spinal cord demonstrated decrease of spasm. The reduction of spasm mentioned above might be significant except for the fact that

even more pronounced relaxation occurred in some patients receiving saline solution.

A request for continuation of injections was considered a strong indication that real relief was being provided. Of those receiving d-tubocurarine, 1 patient asked that the injections be continued, whereas in the group given saline solution 2 made such a request. The 2 patients considered by the observers to be most relaxed by their injections (J M and H F) were in the group receiving saline solution. The false conviction that H F had been receiving d-tubocurarine was so strong that a heated argument ensued, and was resolved only by exhibition of the dosage schedule.

Of the 17 patients given d-tubocurarine, 9 were wrongly estimated to be receiving saline solution. Reference to Table 1 reveals that 5 of these men demonstrated no changes whatsoever attributable to medication. No symptoms were reported and spasms were unabated. One patient complained of intermittent weakness and diplopia. This particular patient, with an incomplete spinal-cord lesion and fair voluntary motion in both lower extremities, demonstrated the most violent and uncontrollable spasms observed on the Paraplegia Service at this hospital. He exhibited no change in spasms, and the mild symptoms of which he complained seemed paradoxical to the observer. Two other patients reported questionable toxic symptoms, with no evidence of improvement.

Seven of the patients given saline solution were incorrectly estimated to be receiving curare. In 3 this inaccuracy was based on the conviction that spasms had been definitely helped, 3 others exhibited no change in spasms but rather marked "toxic symptoms," and in the remaining patient spasms were increased but were accompanied by fairly severe "toxic symptoms."

It is apparent that no significant differences between the control group and the curare group were observed, and it is concluded that no beneficial effects relating to the relief of spasms in paraplegic and paraparetic patients were obtained by the intramuscular injection of d-tubocurarine in oil.

#### SUMMARY

Thirty-four patients with traumatic lesions of the spinal cord were studied in an attempt to evaluate the use of curare in spasticity due to such injuries.

Two independent series were conducted. Seventeen patients received intramuscular injections of 175 mg of d-tubocurarine chloride in oil and white wax every forty-eight hours for ten doses, and 17 were given an equal volume of physiologic saline solution intramuscularly throughout the same treatment period.

No beneficial effects relating to the relief of spasms in paraplegic or paraparetic patients were obtained by the intramuscular injection of d-tubocurarine in oil and white wax.

\*Since this manuscript was submitted for publication Grob et al. also reported a somewhat similar phenomenon accompanying intramuscular injection of d-tubocurarine chloride and these investigators attribute the dermatitis to release of a histamine-like substance.

In neither of the injection series were the observers able to estimate correctly which patients were receiving d-tubocurarine and which were receiving saline solution

The role played by suggestibility in therapy of this type of patient was clearly demonstrated

## RECKLINGHAUSEN'S NEUROFIBROMATOSIS ASSOCIATED WITH INTRATHORACIC MENINGOCELE\*

### Report of a Case

C STUART WELCH, M.D.,† ALICE ETTINGER, M.D.,‡ AND PAUL L. HECHT, M.D.§

BOSTON

WE have recently encountered at operation an intrathoracic meningocele in a patient with Recklinghausen's neurofibromatosis upon whom we had operated fully expecting to find a paravertebral neurofibroma. A search of the literature on the subject of anterior intrathoracic meningocele revealed an interesting association between this lesion and Recklinghausen's disease, which we believe deserves comment since this association is not generally known.

Because of its rarity anterior intrathoracic meningocele is almost never considered in the differential diagnosis of intrathoracic tumor. Groedel<sup>1</sup> mentions the lesion in this connection in his textbook on roentgenographic diagnosis, but otherwise we have found no similar reference. Ingraham<sup>2</sup> observed no anterior intrathoracic meningoceles in the extensive

series reported in his monograph. Almost everyone is confident that a posterior mediastinal or paravertebral mass in a patient with neurofibromatosis is a tumor of neurogenic origin—in all probability, a neurofibroma. The diagnosis of intrathoracic meningocele has not been made before operation as far as we can ascertain, although the diagnosis can probably be made, as pointed out below.

Meningoceles presenting in the sacral region are the most frequent of all those projecting anteriorly. This subject has recently been reviewed by Collier and Jackson.<sup>3</sup> Anterior meningoceles may be found in the cervical and lumbar regions but less commonly than in the sacral area.

A search of the literature on the subject of intrathoracic meningocele reveals accounts of 3 cases,<sup>4-6</sup> to which may be added the case reported below. Two of the previously reported cases of intrathoracic meningocele were found in patients with neurofibromatosis. The addition of the following case accentuates the significance of this association.

## CASE REPORT

A 41 year-old woman with known Recklinghausen's neurofibromatosis was first seen in consultation at the Boston Dispensary on May 14 1947. An intrathoracic tumor had been found in thoracic roentgenograms taken at the time of a respiratory infection 10 months previously. A postero-anterior roentgenogram of the thorax demonstrated a rounded tumor in the thorax adjacent to the mediastinum in the left paravertebral region (Fig. 1) with marked widening of the sixth intercostal space and erosion of the adjacent ribs and vertebral bodies. In addition a fairly well marked kyphoscoliosis was seen. The convexity of the scoliosis was toward the left with its apex in the region of the sixth intercostal space. Distinct erosion of the vertebral bodies and transverse processes adjacent to the tumor (Fig. 2) was also observed.

Physical examination revealed the cutaneous lesions of neurofibromatosis and the spinal deformity previously noted. Examination of the chest was negative, as was neurologic examination. Routine laboratory tests were within normal limits. A diagnosis of paravertebral intrathoracic tumor probably neurofibroma was made. It was thought that a

FIGURE 1. Roentgenogram Showing a Round Tumor Mass on the Left Side Projecting into the Left Lung Field at the Level of the Sixth and Seventh Ribs, with Perfectly Smooth Contours. There is widening of the sixth intercostal space and there are erosive bone changes of the contours of the ribs adjacent to the mass. The findings appeared to be characteristic of intrathoracic neurofibroma.

dumb-bell type of tumor with an intraspinal portion might be present, although there were no neurologic signs. Widening of the sixth intercostal space suggested encroachment of the tumor in this area characteristic of the dumb-bell type.

A left posterolateral thoracotomy was performed on May 24 and the left sixth rib partially resected.

Exposure of the tumor revealed it to be a cystic mass projecting into the thoracic cavity between the sixth and seventh ribs. Its completely smooth and globular nature was evident at once. The posterior parietal pleura was incised and the tumor was observed to be thin walled and to contain fluid. It was dissected down to its base and found to have a neck 3 by 4 cm in diameter which came out of the sixth intervertebral foramen. The diagnosis of meningocele was suspected, and 250 cc of clear spinal fluid normal to character was aspirated from the sac. Complete dissection

of the meningocele was possible down to the leptomeninges of the spinal cord because of the great separation of the neural arches and consequent enlargement of the intervertebral foramen. The meningocele was incised, and its interior was found to be continuous with the subarachnoid space. Adequate visualization of the spinal cord was obtained. No major nerves were contained in the sac, which was excised at its neck. The dura was closed with a layer of interrupted silk sutures. To prevent the leakage of spinal fluid into the

FIGURE 2. Film of the Thoracic Portion of the Spine Showing a Kyphoscoliosis with Convexity toward the Left, the Point of Greatest Convexity Being at the Level of the Sixth Intercostal Space.

There is marked erosion of the lateral and anterior surfaces of the fifth, sixth and seventh thoracic vertebrae and some erosion of the transverse processes of the sixth and seventh vertebrae on the left side together with the previously mentioned erosive changes of the ribs.

thoracic cavity a pedicle graft of the intrinsic dorsal musculature was fashioned and sutured to the edges of the intervertebral foramen. This seemed to fit snugly and to fulfill a real need to ensure a satisfactory support for the dorsal closures. The thoracic closure included the use of a steel suture for the approximation of the fifth and seventh ribs which were widely separated because of the spinal deformity. Catheter drainage of the thoracic cavity was employed for 48 hours. Convalescence was uneventful, and the patient was discharged on the 21st postoperative day. Figures 3A and 3B show lateral roentgenograms taken before and after operation to the latter film the previously noted area of density from the tumor is absent.

Tissue examination of the meningocele sac revealed a cyst wall composed of nerve tissue, pia arachnoid and dura showing fibrosis. The tissue findings were consistent with congenital malformation involving the three structures: nerve tissue, pia arachnoid and dura with cyst formation.

The final anatomic diagnosis in this case was simple meningocele; the wall contained portions of all layers of the leptomeninges.

## PREVIOUSLY REPORTED CASES

In 1933 Pohl<sup>4</sup> reported the case of a forty-seven-year-old woman with Recklinghausen's disease who came to operation with a diagnosis of solid tumor of the mediastinum, probably neurofibroma. At operation a meningocele was found on the right side, which arose at the apex of a kyphoscoliosis in a manner similar to that in the case presented above. Pohl noted a high degree of widening of the intervertebral foramen and called attention to the incidence of spinal-column deformity in Reckling-

meningocele, which was also associated with marked kyphoscoliosis. There was considerable enlargement of the intervertebral foramen and marked erosion of the vertebral bodies.

The third case of intrathoracic meningocele that we have found in the literature was reported by Ameuille, Wilmoth and Kudelski<sup>6</sup> in 1940. A large intrathoracic tumor on the right side, which seemed to emerge between the eighth and ninth thoracic vertebrae and to be situated paravertebrally, was discovered in a forty-eight-year-old woman. Thoracotomy was performed, and a probable diagnosis of

FIGURE 3 Roentgenograms of the Thoracic Area

*The lateral view (A) shows the mass demonstrated in Figure 1 to be situated far posteriorly, the anterior margin projecting scarcely beyond the anterior surface of the spinal column. B shows a postoperative film of the thorax after excision of the meningocele.*

hausen's disease. The operative and roentgenologic findings were confirmed at autopsy, since this patient died of empyema during the postoperative period.

In 1938 Schüller and Uiberall<sup>5</sup> reported the findings in the case of a fifty-six-year-old man with Recklinghausen's disease and a right-sided intrathoracic tumor who came to post-mortem examination. They had previously performed myelographic studies after a suboccipital injection of lipiodol and had perhaps used the only method of diagnosis for intrathoracic meningoceles. Retention of lipiodol was noticed in a dimple at the level of the sixth dorsal vertebra, and, in addition, a spot of lipiodol was seen outside the spinal column and presumably inside the mediastinal tumor. The authors seem to have made the correct diagnosis before death. The patient died after resection of the posterior roots of the sixth, seventh and eighth dorsal nerves, performed for relief of pain. Autopsy disclosed a

hydatid cyst was made at the time of operation. The cyst was punctured, and the orifice packed with gauze. Death occurred from empyema and loss of spinal fluid in the pleural cavity. At post-mortem examination the cyst was identified as a meningocele and the cause of death was attributed to loss of spinal fluid and infection of the pleural cavity. Presumably, this patient did not have Recklinghausen's disease since no mention was made of it in the report.

## DISCUSSION

In the cases of intrathoracic meningocele reported in the literature it is of interest that 2 patients had Recklinghausen's neurofibromatosis and the meningocele was associated with kyphoscoliosis and seemed to arise at the apex of the deformity. The lesion may be congenital, since it is associated with congenital anomalies. Sharpe and Young<sup>7</sup> found cerebral meningocele, spina bifida.

cranial defects and defects in the digits in many cases. Thannhauser,<sup>8</sup> in his review of Recklinghausen's disease, refers to the frequency of developmental anomalies, as do Carriere et al.<sup>9</sup> in their monograph on the subject. Intrathoracic meningoceles, however, have not been specifically mentioned in these reviews. The incidence of paravertebral neurofibromas with or without intraspinal segments (dumb-bell tumors) in patients with Recklinghausen's disease is not exactly known, but it is our opinion that intrathoracic tumors of neurogenic origin are not common.

Blades,<sup>10</sup> in a review of 109 patients with mediastinal tumors operated upon, found thirty tumors of neurogenic origin none of which, presumably, were associated with Recklinghausen's disease. In a review of a collected series of 105 cases of neurogenic tumors by Kent and his co-workers,<sup>11</sup> only 4 patients had Recklinghausen's disease. The relatively low incidence of intrathoracic neurofibromas in patients with Recklinghausen's disease should, therefore, bring the possibility of intrathoracic meningocoele into greater prominence in the differential diagnosis. The incidence of malignant changes was 41 per cent in the cases of intrathoracic neurogenic tumors reported by Kent et al.<sup>11</sup> The uncertainty of the diagnosis represents an indication for operation in these patients. On the other hand, if the diagnosis of intrathoracic meningocoele can be made, operation might be avoided, particularly in poor-risk patients with Recklinghausen's disease.

Intrathoracic meningoceles actually arise as lateral structures, usually projecting through the intervertebral foramina, and then pass anteriorly between the ribs to project paravertebrally into the thoracic cavity, pushing the posterior parietal pleura forward. Their course is quite similar to that of the dumb-bell shaped tumors, which project inside the spinal column, producing a compression of the cord, and into the thoracic cavity.

Naffziger and Brown<sup>12</sup> have called attention to the incidence of the leaking of spinal fluid into the pleural cavity after removal of dumb-bell tumors. The same complication, which may follow operation for meningoceles, was responsible for death in at least 1 of the reported cases.

It seems possible that the diagnosis of intrathoracic meningocoele can be made by myelography, since Schüller and Uiberall<sup>13</sup> have presented evidence that meningoceles in this region can be partially filled and visualized. Eichler<sup>14</sup> was apparently the first to visualize an anterior sacral meningocoele with this method. In patients with Recklinghausen's disease, marked kyphoscoliosis and an intrathoracic tumor, the diagnosis of meningocoele should be entertained and a myelogram performed.

#### SUMMARY

A case of Recklinghausen's neurofibromatosis and an intrathoracic meningocoele is reported.

Of the 3 previously reported cases of intrathoracic meningocoele, 2 occurred in patients with Recklinghausen's disease. The presence of intrathoracic meningocoele should be borne in mind whenever one encounters a patient with Recklinghausen's disease and roentgenologic evidence of an intrathoracic tumor in the paravertebral region, particularly if there is erosion of the vertebrae and ribs and kyphoscoliosis. The position and progression of meningoceles from the spinal column proceed in a lateral and anterior direction, usually through the intervertebral foramen in a manner similar to that of dumb-bell tumors. Meningoceles, however, do not produce spinal-cord compression and neurologic signs. The operative approach for intrathoracic meningoceles is transthoracic. The management of dural closure presents the same problem that exists in the removal of dumb-bell tumors. Closure of the dura must be tight, and in the case reported above, a pedicle graft of the intrinsic muscles of the back was used to reinforce the dural closure.

In the previous reports on intrathoracic meningoceles, all the patients died at operation — 1 after resection of the posterior roots of the dorsal nerves for pain, and the others after direct operative attack on the meningocoele, loss of spinal fluid into the pleural cavity and empyema being the cause of death in these 2 cases.

Myelographic studies may be helpful in certain patients with Recklinghausen's neurofibromatosis and intrathoracic tumors. On the chance that a meningocoele is present, the examiner should try to fill such tumors with opaque mediums by gravity and position changes during myelography in an attempt to demonstrate continuity of the tumor with the subarachnoid space. Failure to fill the tumor by either air or opaque mediums, however, does not disprove a diagnosis of anterior meningocoele.

## EOSINOPHILIC GRANULOMA\*

## Report of a Case with X-ray Evidence of Rapid Progression

WILLIAM J BAKER, M D,† JOHN D HOUGHTON, M D,‡ Egon WISSING, M D,§ AND

REEVE H BETTS, M D ¶

WEST ROXBURY, MASSACHUSETTS

**E**OSINOPHILIC granuloma is a rare disease of bone that has only recently been described as an entity. Approximately 45 cases have been reported in the literature. The condition was simultaneously described in 1940 by Lichtenstein and Jaffe<sup>1</sup> and by Otani and Ehrlich.<sup>2</sup> The former employed the term "eosinophilic granuloma," and the latter "solitary granuloma of bone," to describe the same pathologic process. Otani and Ehrlich's term has largely been dropped, because the lesions are not always solitary and "eosinophilic granuloma" gives a connotation that adds specificity to the mental picture of the lesion. Two previous reports<sup>3,4</sup> in the literature described lesions that, in the light of present knowledge, were probably the same disease as eosinophilic granuloma. It remained for these four authors, however, to collect several cases and present the clinical, x-ray and pathological picture as a distinct disease.

In 1942 Farber<sup>5</sup> and later Green and Farber<sup>6</sup> suggested that eosinophilic granuloma was not in itself a specific disease but was one phase of the progression of xanthomas that ultimately developed into Hand-Schüller-Christian's disease. They presented cases that ran the gamut from what has been described as typical lesions of eosinophilic granuloma to the clinical picture of exophthalmos, diabetes insipidus and lesions of the cranial fossa. In 1944 Jaffe and Lichtenstein<sup>7</sup> reviewed the subject and agreed that eosinophilic granuloma, Letterer-Siwe's disease and Hand-Schüller-Christian's disease were allied, but emphasized the inflammatory aspect. A clinical and morphologic transition from eosinophilic granuloma to Hand-Schüller-Christian's disease has been observed by Engelbreth-Holm et al.<sup>8</sup> in 5 cases. It is not the purpose of this paper to take sides in this controversy. There are many who agree with Green and Farber<sup>6</sup> that this is a metabolic dyscrasia. Others consider it to be an inflammatory disease, possibly infectious, although no etiologic agent has yet been isolated.

## CLINICAL PICTURE

Eosinophilic granuloma occurs more frequently in male than female patients. It is seen most commonly in children and young adults. About 80 per cent of the cases reported in the literature were in children. It is extremely rare over the age of twenty-five. Otani and Ehrlich,<sup>2</sup> in their original paper, reported a case in a thirty-five-year-old man. Versiani, Figueiro and Junqueira<sup>9</sup> reported a case in a fifty-year-old woman who developed a pathologic fracture in the left tibia, biopsy of which showed typical eosinophilic granuloma interspersed with areas of xanthomatous tissue. This woman in addition had diabetes insipidus, although she had no exophthalmos and no cranial defects by x-ray study. She may thus represent an in-between phase as described by Green and Farber.<sup>6</sup>

The disease has certain other characteristics in addition to the age and sex incidence. The lesion may be single or multiple and may involve any of the bones except those of the hands and feet. The ribs and skull, however, are the favorite sites. The long bones are next. One lesion has been reported in the clavicle.<sup>10</sup> X-ray films show rarefied, punched-out areas, which may erode the cortex and in which pathologic fractures may occur. New bone formation may appear secondary to these fractures. There are no associated generalized symptoms, such as fever, malaise and those referable to the gastrointestinal or cardiorespiratory system. Symptoms that are present are due entirely to the local lesion. In the case reported below there was local pain and tenderness. Certain lesions in the skull have led to some of the more bizarre neurologic manifestations.<sup>11</sup> Laboratory examinations are of no help in making a diagnosis. The white-cell count and the morphology of the blood cells are usually normal. Occasionally there is a slight eosinophilia. The blood calcium, phosphorus, acid and alkaline phosphatase and cholesterol levels are normal.

Gross examination of the lesions shows soft granulation tissue, which in places is hemorrhagic, in others yellowish and in still others necrotic, frequently with some destruction and replacement by granulomatous tissue. Microscopically, there are sheets of eosinophils along with phagocytic mono-

nuclear and multinuclear histiocytes. Round-cell perivascular infiltration may be prominent.

The case reported below is interesting from two points of view. The patient, except for the woman of fifty described by Versiani et al.,<sup>9</sup> is to our

FIGURE 1 X-ray Film Taken on April 1 1946 Showing a Cystic Lesion of the Right Seventh Rib

knowledge the oldest thus far reported. What is probably of more interest are the x-ray films. In eosinophilic granuloma the duration of symptomatology is often only a few months. The disease has therefore been considered to be rapidly pro-

FIGURE 2 X-ray Film Taken on April 29, 1946 Showing Erosion of the Cortex of the Rib

gressive. In no previously reported case, however, has this feature been so graphically demonstrated. In two months what originally appeared to be a small benign cyst, measuring 0.5 cm in diameter, became a process that destroyed about 3 cm of rib

Most authors agree that although the usual treatment is local excision and curettage, the lesion can be successfully handled by small doses of x-ray therapy or even by no treatment at all.<sup>6-11</sup> One would have to possess considerable fortitude to have maintained a laissez-faire policy when presented with these x-ray films, not knowing what the lesion showed microscopically. It is our opinion that it is wise to perform a biopsy of any lesion before x-ray treatment or radical or conservative surgery is considered.

#### CASE REPORT

J. L., a 39 year-old shipper entered the hospital on May 18, 1946, complaining of constant pain and soreness in the right anterolateral portion of the chest. About 1½ years before entry he had fallen against a truck and hurt the right side

FIGURE 3 X-ray Film Taken on May 31 1946 Showing Marked Destruction of the Ribs in Two Months

of the chest which had been strapped with adhesive tape, and the symptoms had subsided in 1 week. He was then well until 1½ months before entry when he was seized by a pain in the right side of the chest while lifting a heavy packing case. X-ray films taken in another clinic disclosed a small cystic lesion of the seventh rib (Fig. 1). About 4 weeks later a second x-ray film showed an increase in the size of the lesion (Fig. 2). There was no history of respiratory complaints or of any generalized symptoms. A review of the system was negative.

The past history revealed an attack of rheumatic fever in 1925, with no early or late sequelae.

Physical examination showed a well developed and well nourished man in no acute distress but complaining of soreness in the right anterior axillary line well localized to the seventh rib. There was moderate tenderness in this area, and a depression could be felt in the rib but no soft tissue mass. Examination otherwise was negative.

Examination of the blood revealed a hemoglobin of 18 gm. and white-cell counts of 8600 and 9200 with 55 per cent neutrophils, 34 per cent lymphocytes, 8 per cent monocytes, 2 per cent eosinophils and 1 per cent basophils. Examination of the urine, including tests for Bence-Jones protein, were negative. A Mazzini test was negative.

X-ray films showed a great deal more destruction of the seventh rib than had been present at the examination 1 month previously. In addition there was a fracture through the

FIGURE 4 Enlargement of Figure 3, Showing Detail of the Destructive Process

lesion (Fig 3 and 4). Films of the long bones, skull and pelvis were completely normal.

While in the hospital the patient had an afebrile course. In the early part of his stay the x-ray films taken prior to

FIGURE 5 Postoperative X-ray Film, Showing Partial Rib Resection

admission were not available. For this reason there was considerable discussion about the nature of the lesion presented by the physical findings and x-ray examination in this hospital.

The possibilities mentioned ranged from Ewing tumor and osteogenic sarcoma to multiple myeloma, osteomyelitis and eosinophilic granuloma. When the other films became available, it was generally believed that the lesion was benign but that exploration was warranted in view of the rapid progression of the process.

On June 12, under endotracheal nitrous oxide, oxygen and ether anesthesia, a partial rib resection was carried out. On exposure of the lesion no invasion of the surrounding tissue was found. There was a pathologic fracture through the rather thin bone. Frozen section was made of the tissue obtained at operation and reported as eosinophilic granuloma. The patient made a smooth postoperative convalescence and was discharged from the hospital on June 19.

At follow-up examination 6 months later, the patient was asymptomatic. Physical examination was negative, and recheck x-ray films were normal (Fig 5).

Pathological examination of the specimen revealed a segment of rib 7.5 cm long, 1.8 cm wide and 0.6 cm thick at

FIGURE 6 Photomicrograph of a Typical Section, Demonstrating Eosinophilic Cells at the Periphery and Histiocytes in the Center, a Few of Which Show the Typical Indented Nucleus

the anterior end, and 1.5 cm wide and 0.5 cm thick at the posterior end. The following is a transcription of the pathological report.

There is a slight fusiform dilatation of the central portion through which there is a transverse pathologic fracture, with loss of continuity of the bone. At the widest point the rib is 2.0 cm wide and 1.0 cm thick. The widened part is occupied by an almond-shaped mass of soft, gray-brown tissue, 3.1 by 1.7 by 0.9 cm in diameter, that is fairly well demarcated from the bone at the ends. Anteriorly, the cortex is completely destroyed over the mass, which is covered only by bulging red periosteum. Posteriorly, new white callus, 2 mm or more thick, has formed over the old cortex, and appears to be infiltrated with gray-brown tissue in its inner portion. This tissue extends grossly only as far as 1.7 cm from the anterior end and 2 cm from the posterior end of the specimen. It perforates the cortex at the posterosuperior edge of the rib, but does not appear to pass beyond or through the periosteum at any point.

Microscopical examination of the soft yellow-brown central tissue shows vascular granulation tissue containing follicle-sized foci of loosely arranged histiocytes with large pale nuclei, occasional multinucleate (giant) cells, massive infiltration with eosinophils and lymphocytes in

equal or lesser numbers (Fig 6). There is an area of necrosis centrally. Peripherally there is a transition into dense scar tissue with fibrous endarteritis. Perivascular lymphocytic infiltration and macrophages containing old blood pigment extend into the adjoining skeletal muscle. The diagnosis was eosinophilic granuloma of bone (benign).

### SUMMARY

The literature on eosinophilic granuloma is briefly reviewed.

A case in a thirty-nine-year-old man is presented. X-ray films showed a very rapid progression of the disease in the course of two months.

## A SEVERE REACTION TO TETRAETHYLAMMONIUM CHLORIDE

ALLAN L. FRIEDLICH, JR., M.D.,\* WILLIAM P. CHAPMAN, M.D.,† AND JOHN B. STANBURY, M.D.‡

### BOSTON

**T**ETRAETHYLAMMONIUM salts have been found to block efferent autonomic impulses at both the sympathetic and parasympathetic ganglions.<sup>1,2</sup> Because of this action, the drug is being employed in a variety of clinical studies. The effect of tetraethylammonium ion in man has been described by Lyons and his associates,<sup>3-5</sup> who have administered the drug over a thousand times with "very few serious effects." They make particular reference to the occasional profound fall in blood pressure and transient vascular collapse in patients with malignant hypertension who have received tetraethylammonium parenterally. Otherwise, there has been no report of a severe untoward reaction to this drug. In the course of studies on hypertensive patients and on intestinal motility at the Massachusetts General Hospital,<sup>6</sup> tetraethylammonium ion had been given nearly a hundred times before a severe reaction occurred. The purpose of this communication is to report the reaction in detail.

### CASE REPORT

A 37-year-old nulliparous housewife entered the hospital for the investigation of abdominal pain. She had undergone five abdominal operations for pelvic inflammatory disease, which had resulted in the cessation of menses and the occurrence of hot flashes in 1934. Several years later she began to have attacks of severe epigastric and right upper-quadrant pain which radiated through to the tip of the right scapula and to the right shoulder. These attacks were accompanied by nausea and vomiting. Cholecystectomy revealed an inflamed gall bladder but no gallstones. She felt well for

18 months but thereafter continued to have episodes of pain similar to those preceding the cholecystectomy. In 1942 she was seen for the first time at this hospital, where a common duct exploration was advised, but was declined by the patient. At that time the blood pressure was 120/70. After this admission she had infrequent pain. In 1946 frequent attacks of epigastric and right upper-quadrant pain radiating to the right scapula and shoulder again developed. During such an attack accompanied by severe vomiting she re-entered the hospital.

Physical examination was remarkable only for an olive blot of the skin and multiple abdominal scars. The blood pressure was 110/70. Laboratory findings including a gastrointestinal series, barium enema, intravenous pyelogram, duodenal drainage, serum amylase and all liver-function tests were within normal limits. Because of the obscure nature of the pain, intestinal motility studies were done by one of us (W. P. C.) using distensible balloons placed to the upper portion of the small bowel. The blood pressure previous to the test averaged 105/70. The intravenous administration of 0.6 mg of atropine abolished the intestinal contractions and relieved the abdominal pain. The distention of a balloon immediately below the ligament of Treitz reproduced the right upper-quadrant pain but without its usual radiation.

On the following morning the patient was given tetraethylammonium chloride with the intestinal balloons in place, to observe the effect on the pain of abolishing intestinal contractions with this agent. Before the injection the blood pressure and pulse rate were recorded at 2 minute intervals for 10 minutes. The blood pressure averaged 120/80 and remained nearly constant. The average pulse rate was 75. The abdominal pain was then of moderate to severe intensity. Tetraethylammonium chloride, to a dosage of 230 mg was given intravenously at a rate of 100 mg per minute. The patient was hyperventilating slightly immediately before the injection. This increased markedly during the administration and immediately thereafter. Within 1 minute after the injection had been begun, the intestinal contractions ceased with complete relief of pain. At that time the blood pressure was 115/85. After 230 mg of the drug had been given, the blood pressure fell to 75/55, with a pulse rate of 80. Because of this decrease the remainder of the contemplated dosage of 300 mg was not given. Within the next 30 seconds the patient complained of numbness and weakness, became dyspneic and pale, and then sat up exhibiting ineffectual,

\*Assistant resident, Medical Service, Massachusetts General Hospital.

†Research fellow in psychiatry, Harvard Medical School; assistant Department of Medicine, Massachusetts General Hospital.

‡Research fellow in pharmacology, Harvard Medical School.

gasping respirations of an alarming nature. She later stated that at that time a large flash of light had appeared before her, after which "everything went black." The blood pressure was 68/48, and the pulse rate 96. Epinephrine (0.2 cc of a 1:1000 solution) was given intravenously, after which the blood pressure rose to 102/76 and the pulse rate to 108 per minute. The respiratory distress was relieved, and she felt better. Within 4 or 5 minutes the blood pressure again fell to 68/54, the respiratory distress returned, and 0.1 to 0.2 cc of epinephrine was again given, in addition to oxygen by mask. During the next 15 minutes this sequence of events was repeated three times. Because the pulse rate rose to 140, neosynephrine was substituted for epinephrine on a subsequent occasion, and an intravenous infusion of 1000 cc. of 5 per cent dextrose in water was started. Fifteen minutes after the administration of tetraethylammonium chloride the patient complained of inability to move the legs, which persisted for 20 minutes. At about the same time she had well marked carpopedal spasm and a positive Chvostek sign, which were dispelled by rebreathing. Thirty-five minutes after the injection of tetraethylammonium chloride, intestinal contractions returned to their previous normal level. Nevertheless, the blood pressure remained at 70/40, with a pulse rate of 140. Over the next 2-hour period the blood pressure was hardly obtainable, and the patient continued to complain of marked weakness. An electrocardiogram revealed a perfectly regular rhythm at a rate of 190, which did not vary with carotid-sinus pressure. Small upright P waves immediately preceding the QRS complexes could be seen only in the special auricular Lead 3. The duration of the QRS complexes was 0.08 second, and they were of small amplitude. The ST segments were sagging in Leads 2 and 3, and the T waves were essentially flat in all conventional limb leads. These findings were interpreted as representing rapid paroxysmal auricular tachycardia. The arrhythmia persisted for 18 hours, reverting to normal rhythm at a rate of 110 per minute after a test dose of 75 mg of quinidine lactate given intramuscularly. Throughout the acute episode the patient remained fully conscious, and the skin remained dry.

During the afternoon of this severe reaction, the patient received 600 cc. of plasma and 500 cc. of whole blood, after which the blood pressure stabilized at 90/60. Despite the reversion to a normal heart rate and rhythm, the blood pressure remained at levels averaging 80/65 on the 1st day, 80/60 on the 2nd day, and 80/55 on the 3rd day after the administration of tetraethylammonium chloride. Subjectively, the patient gradually improved, and the blood pressure rose to 90/60 on the 9th day at the time of discharge from the hospital.

One month later the patient was readmitted for further studies, which failed to elucidate the cause of the severe reaction to tetraethylammonium chloride. During this admission the blood pressures averaged 100/65. Liver-function studies were again negative. An extensive laboratory evaluation of the endocrine status, including, among other procedures, a Wilder test, determinations of 17 ketosteroids, 11 oxysteroids, serum sodium and potassium, and inspection of the rate of axillary-hair growth, revealed values within normal limits except for a basal metabolic rate averaging -22 per cent and an elevated urinary output of follicle-stimulating hormone (the last finding was consistent with the menopausal state). The diagnoses on discharge were possible biliary dyskinesia, menopausal syndrome and psychoneurosis. At a subsequent laparotomy the common duct was normal except for a somewhat constricted sphincter of Oddi, multiple adhesions involving the upper portion of the small intestine and a dilated duodenum.

### DISCUSSION

It appears that the administration of 230 mg of tetraethylammonium chloride given to this patient

produced a severe immediate reaction, which was characterized by profound hypotension and an alarming degree of respiratory distress. The hyperventilation may have been on the basis of anxiety, but Lyons et al.<sup>4</sup> described 4 female patients who developed sudden hyperventilation after the administration of this drug. They also reported transient inability to move the legs, a feature that this patient presented. The persistence of hypotension for several days cannot be definitely ascribed to the drug, since the return of intestinal contractions occurred in the usual time,<sup>8</sup> suggesting that the tetraethylammonium ion had been largely eliminated. The paroxysmal tachycardia could be attributed to the drug, to the use of the vasopressor drugs or to the patient's unstable emotional state.

The manner in which such an unfortunate reaction to the drug may be avoided by proper selection of cases is beclouded by the many features that characterized this patient. She was a small, asthenic, emotionally unstable woman with a low-normal blood pressure, who had symptoms and laboratory evidence suggestive of the menopause and of hypothyroidism. Whatever the mechanisms involved, the fact remains that the patient experienced an untoward reaction to the administration of tetraethylammonium chloride of such severity as to cause grave concern. The possible occurrence of such a reaction is called to the attention of those using the drug or contemplating its use.

### SUMMARY

The action of tetraethylammonium chloride in man is briefly discussed, and the literature briefly reviewed.

A case of a severe untoward reaction to the drug is reported.

## MEDICAL PROGRESS

### TECHNICAL ADVANCES IN PHYSICAL MEDICINE

ARTHUR L. WATKINS, M.D.\*

BOSTON

IN RECENT years those concerned with developments in the field of physical medicine have rightly emphasized the need for fundamental research, and a number of investigative and training centers have been established with this in mind.<sup>1</sup> Reviews of current research in physical medicine have been the subject of previous reports in this series<sup>2</sup> and elsewhere.<sup>3</sup> Physical medicine is best known, however, for its therapeutic activities, and certain developments in technic constitute the basis of the following report.

#### PROGRESSIVE-RESISTANCE EXERCISES

Therapeutic exercise can be considered the most frequently utilized and probably the most valuable single procedure in this specialty. It is accordingly of some significance to report an advance in technic of application. DeLorme,<sup>4</sup> while serving in the Army Medical Corps, reported the successful adaptation of the system of muscle training of professional weight lifters to restore maximum function to weak, atrophied muscles after certain types of disease and injury.

The basic principles of this system may be simply stated. To produce power in a muscle—that is, ability to lift heavier loads—the training exercises should be with heavy resistances and few repetitions. In contrast, endurance is developed by low-resistance exercises with frequent repetitions as with stationary bicycle riding. This method of heavy-resistance, low-repetition exercising was found by DeLorme to develop muscular power to a remarkable degree, as evidenced by ability to lift greater weights and by actual muscular hypertrophy according to circumferential measurement. The speed of such muscular development was much more rapid than that observed with the conventional type of exercises.<sup>4</sup>

#### Exercise Program

The exact exercise load for any patient is based on his maximum effort as recorded once a week on the test day. At the beginning of the program weights are gradually added to the load upon the exercised muscle until the maximum that can be moved ten times through the full range of motion is determined. This is designated as the 10-repetition maximum (10 R M). The exercise work schedule for the following week is based on this determination.

In the original papers by DeLorme<sup>4</sup> the work program consisted of a series of exercises, usually with seven to ten sets of different weight lifts repeated ten times each as the daily exercise stint. Exercise was started with lighter loads and ended with ten lifts at the 10-repetition maximum. Once a week on the test day the 10-repetition maximum was determined, which usually increased, and also the 1-repetition maximum (1 R M), or the greatest weight that could be lifted once through the full range of motion. In some cases, as in joint instability, incomplete healing of wounds or arthritis, the determination of the 1-repetition maximum was omitted. The usual weekly schedule consisted of the daily exercises with the same prescribed weights and frequencies until the test day, after which there were two days without any exercise. Only one exercise period a day was permitted.

#### Results

In the first series of patients reported by DeLorme emphasis was placed on development of power of the quadriceps muscle. The types of cases treated included unstable knees from tears of cruciate and collateral ligaments and after removal of the menisci, as well as fractured femurs and patellas, recurrent dislocations of the patella and atrophy of the quadriceps from prolonged immobilization from fractures in the vicinity of the knee joint or other injuries necessitating immobilization. He found that in a series of patients the average time required to restore normal power to the extensor mechanism of the knee was nineteen days. It was also observed that such heavy-resistance exercises were more satisfactory than weight-bearing exercises before full muscle strength had been regained. At the same time increase in the range of knee motion was coincident with the increase in muscular power, the range of motion closely approaching normal unless gross damage of articular surfaces was present.

This principle of relatively maximal resistance with minimal repetitions as advocated by DeLorme has been put to clinical test in a variety of conditions beyond those of trauma to bones and joints. Preliminary studies in patients with residual weakness from poliomyelitis have indicated that muscle groups previously with power of only 20 to 50 per cent of normal may be able to increase their functional capacity to a significant degree.<sup>5</sup> This was found true even in cases of long standing paresis.<sup>6</sup>

\*Associate in medicine, Harvard Medical School; chief of physical medicine, Massachusetts General Hospital.

when careful measurement of muscle strength was made by means of ergographic tracings, maximum-effort test, spring-gauge test and circumferential measurement of muscular volume. The rapidity of improvement in muscular strength in these long-standing cases of poliomyelitis was, as might be expected, considerably slower than that in patients suffering only from weakness of disuse atrophy. It was also observed that improvement in muscle strength was not sufficient to cause an increase in grading according to the usual manual scale, although significant changes were observed in the maximum-strength tests and ergographic tracings. It was further noted that the patients reported coincident improvement in functional ability in ordinary tasks such as ability to walk greater distances without fatigue.

### *Physiologic Studies*

As might be anticipated, this method of exercise was soon investigated by physiologists on normal persons, particularly because of the empiric origin and nature of the training regime employed. At the Baruch Center of Physical Medicine at the Medical College of Virginia a group of normal persons were subjected to a period of training with heavy-resistance exercises following the DeLorme technic involving the motions of knee extension and elbow flexion.<sup>7</sup> In this study the daily work unit consisted of 70 to 100 contractions divided into bouts of 10, with rest pauses between the series of repetitions as originally proposed by DeLorme, the last series not surpassing the 10-repetition maximum. The study period consisted of not less than four weeks of exercise, and the criteria of improvement were obtained by the maximum efforts put out on the test days — namely, the 10 R M or the 1 R M. The results obtained suggested that the most important single element leading to increase in work output was the will to perform a physiologic maximum effort. Daily exercise of this sort was found to produce a significant increase in work done on each weekly test day, and the improvement in work capacity under such a program of heavy-resistance exercise was rapid, for strength more than doubled in four weeks of systematic training. The increased work capacity was also found to continue during a post-exercise period, which exceeded in duration the initial period of training, in fact, the ability to perform work might continue to improve after the cessation of systematic training, suggesting a type of motor learning including extension of the psychologic end point of fatigue.

Further studies of a similar nature from the same laboratory are of considerable interest.<sup>8</sup> In another experiment normal adults were subjected to a series of heavy-resistance exercises to a single upper or lower extremity, and the changes in the contralateral limb were observed. Such exercises, which rapidly

increased the strength of the exercised limb, had a corresponding effect on the contralateral unexercised extremity, although the results were less marked. It was believed that the determining factor in this so-called "cross education" was the severity of the effort evoking the response rather than the duration of the exercise. It was suspected, however, that the unpracticed side received many reflex stimuli, which acted upon it to evoke widespread synergistical contraction. The results of this study suggested that such "cross education" might serve as a useful therapeutic tool in cases in which volitional control is unilaterally defective or in which contralateral muscle groups are rendered temporarily inaccessible through immobilization.

### *Technic of Exercise*

Because so little detailed information is available concerning the use of this exercise equipment, particularly as applied to the weaker grade muscles, some of the important technical aspects are discussed. In relation to counterbalancing in exercises two terms must be defined: the "exercise load" and the "muscle load." The exercise load is the load that is placed upon the weight pan of the apparatus and does not necessarily refer to the resistance placed upon the muscle, since in some cases it is used as counterbalance. The muscle load is the actual resistance the muscle must overcome during the exercise. For strong muscles the muscle load includes the weight of the extremity and the exercise load. For weak muscles the muscle load is still near the maximum for that muscle but less than the weight of the extremity, for the exercise load serves as a counterbalance. When the exercise load is used as counterbalance it never exceeds the weight of the extremity, thus producing passive motion, but is always within the range necessitating maximum voluntary effort. The term "load-assisting exercises" has been applied to procedures in which the exercise load assists the muscle, and "load-resisting exercises" to those in which the load resists the muscle.

With load-resisting exercises the work increase for the week is based, as mentioned above, on the 10-repetition maximum. With load-assisting exercises the exercise routine is based on the 10-repetition minimum, which is determined by tests for the smallest load on the weight pan that still permits the muscle to perform not more than 10 repetitions while doing a load-assisting exercise. As muscle strength increases it can be seen that the exercise load will decrease. The opposite is true in case of load-resisting exercises. It has also been found when dealing with these weaker grades of muscles that the daily exercise prescription, instead of being from 70 to 100 repetitions, may be reduced to three sets of 10 repetitions or even less. An approximate scheme for determining exercise loads is as follows:<sup>9</sup>

**Load-resisting exercises**

First set of 10 repetitions  
Second set of 10 repetitions  
Third set of 10 repetitions

A half of 10-repetition maximum  
Three fourths of 10-repetition maximum  
10-repetition maximum

**Load-assisting exercises**

First set of 10 repetitions  
Second set of 10 repetitions  
Third set of 10 repetitions

Takes the 10-repetition minimum  
One and a half times the 10-repetition minimum  
10-repetition minimum

With improvement in strength it is possible simply by readjusting the pulley arrangement to change from load-assisting to load-resisting exercises, thus continuing the principle of progressive resistance exercises with near maximum resistances of few repetitions at all times (Fig 1)

**MICROWAVES ("RADAR")**

High frequency electrical currents have been used in medicine and surgery for over fifty years. It was demonstrated, particularly by d'Arsonval, that frequencies above 10,000 cycles per second produce no evident effect beyond that of heating the tissues through which they pass. Frequencies in the neighborhood of 1,000,000 to 3,000,000 cycles per second or long-wave diathermy began to be employed about 1900 and are still in use. Over 10 years ago the frequencies were increased to clinical generators to the neighborhood of 10,000,000 cycles with a wavelength of 30 meters or less (short-wave diathermy). Then frequencies of 100,000,000 cycles were produced, or wave lengths of 3 meters. They were called ultra short-waves. Electronic developments have now made it possible to apply frequencies of 3,000,000,000 cycles of wave lengths of 10 cm., which have been called microwaves and are related to radar of wartime prominence. Although radiations of such frequencies and wave lengths were produced before the war, it was not until recently that their possible usefulness in medical practice could be determined.

**Physical Characteristics**

Certain physical properties of microwaves can be contrasted readily with radiations of lower frequency in the radio-frequency spectrum. Microwaves have optical properties, for they can be reflected, refracted and diffracted. They can also be focused by suitable lenses and reflectors much as the beam of a searchlight. Microwaves may be selectively absorbed, but the biologic significance of this is still unknown.

This high-frequency energy cannot be transmitted from and to antennae in the usual fashion of a lower frequency but is transported along hollow pipes or coaxial cables, known as wave-guides, which must be carefully designed according to the frequency used. Certain meteorologic conditions in nature may act as wave-guides, and during the war the pulse-echo system was used to determine the location of enemy targets with radar. Therapeutically, however, energy is continuously rather than intermittently transmitted.

It has been found that the absorption factor of water at 100°F for microwaves at a frequency of

2450 megacycles per second — that assigned by the Federal Communications Commission — was approximately seven times greater than that of the usual short-wave frequencies of 27 megacycles. There is thus experimental physical evidence of the possible efficiency of this type of energy for heating purposes, provided the output is sufficient and properly controlled and directed.

**Experimental Studies**

One of the first published reports on the effects of microwaves on living tissues comes from the Mayo Clinic.<sup>10</sup> The results of these studies on dogs indi-

FIGURE 1 Exercise for Strengthening Neck Back Muscles. Hyperextension is made possible by counterbalance (A) in addition to the patient's maximum muscle power.

cated that microwaves were an effective heating agent. Rises of cutaneous temperature between 3 and 5 degrees were accomplished in twenty minutes with moderate output. Corresponding rises in subcutaneous and muscular tissue were also observed. Measurements of circulation were made with a bubble-flow meter that indicated increased venous return from the heated extremities. No unusual effects were observed other than those to be expected from the corresponding rises in temperatures of the tissues.

The Council on Physical Medicine has also investigated the microtherm generator produced by the Raytheon Manufacturing Company and has placed it in its list of accepted devices.<sup>11</sup> In experiments reported on human volunteers with measurements of deep-muscle temperatures it was found that increases to 103.5 to 105°F were obtained. It was noted that the sensation of cutaneous warmth was less than that usually expected by other means of

heating to a similar degree and that, for a given degree of cutaneous irritation, the rise in deeper tissue temperatures by microwaves was much greater than that produced by radiant heat

I have used an early model of the Raytheon microtherm\* over a period of a year. It has been utilized for heating purposes in a variety of conditions in the ordinary practice of physical medicine, including subdeltoid bursitis, radial humeral bursitis, non-suppurative tendinitis, muscle strain and contusion, and sinusitis. The usual technic of application included exposure for twenty minutes, which resulted in comfortable warming reported by the patient and increase of cutaneous temperature with mild erythema. Patients were warned about the sensation to be expected and were told to report undue warmth as with any heat treatment. No cases of blistering, burning or untoward effects were reported. An occasional patient felt increased discomfort in an acute bursitis in no wise different from that often resulting from short-wave diathermy. The results obtained are of no statistical significance, but from this period of clinical observation it is believed that this is a safe and effective means of supplying heat

\*Kindly supplied by the Raytheon Manufacturing Company, Waltham

to a localized area when employed with similar precautions applying to the use of diathermy. The opportunity to see the skin at all times during treatment is a technical advantage in avoiding excessive heating. This new electronic development appears to be a worthy addition to the therapeutic armamentarium of physical medicine. Further physiologic and clinical studies are indicated.

#### CASE 34181

##### PRESENTATION OF CASE

A twenty-year-old housewife was admitted to the hospital complaining of lassitude and a movable lump in the abdomen.

Two years before admission the patient became pregnant and had a normal prenatal course for the first six months. At that time while at rest she had an episode of sudden severe pain low in the lumbar region, without any radiation and lasting twenty minutes. There was no dysuria, passage of stool or pain in the lower abdomen or genital region. At one other time during pregnancy she was said to have passed bloody urine. However, she had no urinalysis during pregnancy. She had pruritus vulvae and burning on urination during pregnancy. After parturition she had dizziness, which was cured by glasses. She had felt complete

lack of energy and had liver injections without effect. She ate heavily but could gain no weight (the weight was 125 pounds and during pregnancy it had been 142 pounds). Occasionally she had panicky feelings and spontaneous crying spells. She noted the presence of a slightly tender, movable lump in the right lower abdomen. She complained occasionally of mild shooting pain of right-obturator-nerve distribution. For two years during evening devotion she could not kneel and then lean forward because of pain in the midlumbar region. She had mild mucoid vaginal discharge.

There was no history of tremor, palpitation or heat intolerance. Her husband had "depressive spells," and they had been separated twice. The patient had a family history of diabetes. Six members of her family had "stiffening and fixation of the lower spine."

Examination revealed a pale, well developed, well nourished woman. There was a precordial systolic thrill and a Grade III systolic murmur best heard at the apex. There was tenderness over the right costovertebral angle and a tender, firm, 3-cm. mass in the right midportion of the abdomen. The mass was considered to be in the position of a ptotic kidney or caudate lobe of liver. It did not move with respiration. The right kidney was palpable and descended to the midportion of the abdomen. The left kidney was not felt. The cervix was lacerated, and the uterus retroflexed. There was slight adnexial tenderness. Reflexes in the legs were normal.

The temperature, pulse and respirations were normal. The blood pressure was 130 systolic, 85 diastolic.

Examination of the blood showed a hemoglobin of 38 gm and a white-cell count of 7800. The differential count was within normal limits. Urinalysis was negative. The lumbar spine was radiologically normal. An excretory urogram showed the kidneys to be normal in size, shape and position. The dye appeared promptly in both urinary tracts. There was no definite abnormality of calyces and pelves. The right ureter was somewhat kinked at its upper extremity, but this caused no obstruction. A film taken in the upright position showed both kidneys to descend about 5 cm. A barium enema revealed no intrinsic abnormality or external compression. An ill defined shadow was noted on the right side of the abdomen below the right kidney partially obscuring the shadow of the right psoas muscle. Lateral films taken at another hospital showed the presence of a mass below the right kidney, displacing the ureter medially and anteriorly.

On the fifth hospital day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR. RICHARD SCHATZKI\* It does not seem out of place to start with the x-ray films. We shall first look at the films taken at the other hospital, about two weeks prior to admission. The films with catheters in both ureters show the left ureter in approximately normal position and the right ureter to be displaced far medially and overlying the spine. The shadow of the left psoas muscle is clearly visible, the right is visible but not so well defined. I cannot see a definite soft-tissue mass. The right kidney is well outlined and appears normal in size and shape. After injection of dye through the catheters normal kidney pelves are seen on both sides. The right ureter still maintains its position over the spine even after the catheter has been withdrawn partially, its displacement starts at the ureteropelvic junction. The lateral film shows the kidney in normal position, but the ureter, starting at the ureteropelvic junction, seems to be displaced forward. The films taken at this hospital show again a normal appearing kidney. The shadow of the left psoas muscle is clearly outlined, the right is outlined a little more clearly than on the films taken elsewhere. On some of the films I think I can see something that looks like a mass below the kidney, but this is by no means definite. There is disturbingly little visible to suggest a mass. The intravenous pyelograms do not outline the ureters well enough to determine their position. The upper end of the ureter on the right side shows some displacement forward as on the outside films,

and we will therefore assume that the ureter had the same position as on the previous examination.

A barium enema was performed and was said to be completely normal, without displacement of the colon. It is difficult to make a statement of displacement of the intestines from films unless there are a number of them or the displacement is quite marked, and I hesitate to express an opinion about anything that is so vaguely seen, but on these films I have the impression that the ascending colon is slightly more to the right than usual. In both these films after evacuation the whole colon drops down normally, there is no fixation of the colon anywhere. Of interest is the lateral film that was taken apparently after evacuation of the enema, and the thing that impresses me is that there seems to be a difference in the size of the abdomen compared with the films taken approximately two weeks previously. I measured the distance from the anterior abdominal wall to the anterior aspect of the spine on both films, and it certainly is greater on the recent film. The patient apparently was a slender woman, and very slight changes in position of the patient may influence the measurable thickness of the abdomen. So I do not know that we are justified in taking this difference in size of the abdomen as a definite fact, otherwise, it would be extremely interesting. That is as far as we can go on the x-ray appearance.

What conclusions can be drawn from the evidence so far? The logical conclusion is that this patient had a mass in the retroperitoneal space on the right side, which displaced the right ureter forward and to the left. There are many lesions in the retroperitoneal space that can produce such a displacement. There are numerous benign tumors that may occur there, the most common one probably being a neurofibroma. Could this have been a neurofibroma? The location is consistent. The patient's history would certainly go with the diagnosis. The patient had one attack of severe pain, which is unusual. She had occasional pain in the distribution of the obturator nerve, which runs along the medial aspect of the psoas muscle in the region where the pathologic lesion appears to be. We do not see any defect in the spine. A neurofibroma anywhere near the spine, even originating from the spine, does not have to deform the spine, and certainly in the abdomen, where there is so much space for a tumor to grow, it would not cause pressure defects in the spine. There are a few disturbing features about the diagnosis of neurofibroma. The first is that I cannot see the tumor on the plain films — disturbing for a tumor of this size. The other disturbing feature is the fact that clinically the mass is described as being 3 cm in diameter. If what was felt clinically coincides with what we believe to be the lesion in these films, the mass should be larger than 3 cm. Of course it is possible that the clinical mass represented only a portion

\*Radiologist, Mt. Auburn Hospital, Cambridge, Massachusetts.

of the x-ray mass, which would go well with neurofibroma, since neurofibroma is often lobulated. Neurofibroma is still a good possibility.

What other retroperitoneal tumors may occur? There may have been a lipoma in the retroperitoneal tissue. That would explain nicely why we see so little of the tumor mass. On the other hand we do not see any radiolucency, such as one would expect from a lipoma in this location. Against lipoma is the fact that the mass was readily palpable by the patient. I would rather believe that that makes the diagnosis unlikely.

Another mass in the retroperitoneal region in that area could be a cyst originating from the kidney. Cysts may originate particularly from the lower pole of the kidney, and the kidney shadow may appear to be perfectly normal, if the cysts are pedunculated. A pedunculated cyst of the lower pole of the right kidney could produce this picture. Again, it is rather surprising that we do not see a definite mass on the plain film.

There are all kinds of other queer tumors that may occur in this location. It is an interesting embryologic region. The wolffian and müllerian ducts may leave cysts behind. There are occasional cysts of the ureter, ovarian cysts and so forth. I do not know how one can make a definite diagnosis of any of these lesions. There are other benign tumors that I am sure may occur.

We have of course the possibility of malignant tumors, metastatic cancer may occur retroperitoneally. We do not have to worry too much about this possibility since the lesion had not changed much in two years' time. I do not believe that we can rule out a slowly growing sarcoma, fibrosarcoma or neurofibrosarcoma—in other words, a tumor similar to the first tumor that I mentioned, neurofibroma, only its malignant variant.

Another tumor in this area is the teratoma. I would not try to make a diagnosis from the evidence at hand. Dermoid cyst belongs to the congenital ones that I have already mentioned.

Was this lesion necessarily a tumor? An abscess in the retroperitoneal space would produce the same displacement of the ureter. There is nothing in the history to suggest abscess. A hemorrhage into the retroperitoneal space could produce such a displacement. Again, there is nothing in the history to suggest that the patient had a hemorrhage, although I think it is possible for someone to have a hemorrhage without any dramatic clinical story to go with it. That would explain the displacement and would explain why we see so little of a soft-tissue mass. I do not believe that we can rule it out, but with the negative history it is definitely a long shot.

Is it necessary to suppose that what we see had anything to do with the patient's complaint—not the lassitude, but the lump? It is possible that what we see is a red herring and that the patient

had an additional mass in the peritoneal cavity—a tumor of the small bowel 3 cm in diameter. Displacement of the ureters may occur with other conditions than masses, as we have already said. The ureter may be pulled over by a scarring process or by loss of substance on the side to which the ureter is pulled. Again, we have nothing to suggest this course of events. It would be helpful to find something in the peritoneal cavity that would explain the free mobility of the mass. On the other hand, the free mobility was an observation of the patient, there was no statement by the doctor that the mass was movable. Some mobility is possible in retroperitoneal tumors. The normal pancreas and the normal kidney have definite mobility. Pedunculated tumors may have a good deal of mobility. You may remember a case taken up at one of these conferences in which the discussor was led astray by just this fact—a pancreatic cyst that was freely movable, which had caused the discussor to rule out a retroperitoneal mass.

We have not enough evidence on which to base the possibility of an intraperitoneal mass.

I shall make a diagnosis of retroperitoneal mass. I do not know its histology. I shall place neurofibroma first and question of cyst of the lower pole of the kidney second, but I know very well that I have no right to make a histologic diagnosis.

DR WILLIAM A. CLARK: Will Dr. Schatzki comment on whether or not the sacroiliac joints look normal? Much of the symptomatology might be explained on the basis of mild rheumatoid spondylitis.

DR SCHATZKI: I would call them normal.

DR RONALD C. SNIFFEN: Do you agree with Dr. Schatzki's reasoning, Dr. Wyman?

DR STANLEY M. WYMAN: I agree completely.

#### CLINICAL DIAGNOSIS

Retroperitoneal tumor

#### DR SCHATZKI'S DIAGNOSIS

Retroperitoneal mass

Neurofibroma?

Cyst of lower pole of kidney?

#### ANATOMICAL DIAGNOSIS

*Ganglioneuroma, retroperitoneal*

#### PATHOLOGICAL DISCUSSION

DR SNIFFEN: Dr. Dobyns, you took care of this patient? Will you tell us what you know about her?

DR BROWN M. DOBYNS: Operation was performed by Dr. Oliver Cope. The patient was sent in in the belief that she had a tumor, probably above the kidney. The mass that was felt was thought to be the kidney. The x-ray films (retrograde pyelograms) that you have seen did not accompany the patient when she arrived. After a number of days of study she was about ready to be discharged because of lack of positive evidence that could be obtained.

Then we sent for the x-ray films, thinking that the doctor's idea that there was something in the renal region might be confirmed. The displacement of the ureter was well demonstrated in the retrograde pyelograms. Exploration was accomplished through a right transverse abdominal incision. The ascending colon was pushed forward by a mass, which was exposed by reflecting the right colon and cecum medially. The mass had several long fingers of tissue that extended upward and posterior to the vena cava, wrapping around and adherent to it. At the upper end this extended almost behind the liver. There were several secondary masses about the size of a golf ball in the connective tissue immediately adjacent to the main tumor. The whole mass was dissected out from above downward. We tied off a number of small vessels leading from the tumor to the vena cava. The mass was found to arise on a pedicle that came through a small aperture in the psoas muscle. It came through at the level of the third lumbar vertebra. This aperture is the usual anatomic pathway of the sympathetic commissure. The tumor was not adherent to the anterior branches of the lumbar plexus. It had no obvious relation to the obturator nerve or the anterior femoral cutaneous nerve, and it was thought that the tumor arose from sympathetic-nerve tissue because the sympathetic trunk was not present after removal of the tumor. The tumor was thought to have been completely removed.

DR SNIFFEN Did you think that the neoplastic tissue had multiple points of origin or was a single lobulated tumor?

DR DOBYSN We believed when we removed the specimen that there was a moderate amount of freedom between the secondary tumor nodules and the main mass. They were close enough to the main mass to have had some continuity.

DR SNIFFEN The tumor that Dr Cope removed was a lobulated, encapsulated mass. Microscopical sections showed a dense background of nerve fibers in which ganglion cells were embedded. In short, the tumor was a ganglioneuroma. As you know, the ganglioneuroma is the most highly differentiated tumor arising from the anlage of the autonomic nervous system. Usually, it is found in the adrenal medulla or along the line of the paravertebral ganglions. Metastasis does not occur, but multiple tumors are not a rarity. In neuroblastomas, which are the undifferentiated tumors of the sympathetic anlage, one occasionally finds areas of differentiation into ganglioneuroma. I should think that the prognosis is excellent in this case.

#### CASE 34182

##### PRESENTATION OF CASE

The patient was a full-term baby girl born in the hospital after a normal labor of twelve hours by a para V mother.

The pregnancy was uneventful. The mother was sedated with seconal (0.3 gm), amytal (0.4 gm), and scopolamine (0.4 mg). The child was born with the cord around the neck. The body was pink, and the head blue. She was reported to have cried spontaneously. The birth weight was 6 pounds, 15 ounces, and the length was 20 inches.

The mother's third child had died shortly after birth of atelectasis.

The baby was put in an incubator and given continuous oxygen because the color was dusky. Seven hours after birth she seemed to have some difficulty in breathing. Suctioning of mucus resulted in improvement for the next four hours. At that time, eleven hours after birth, the baby, who was being observed by the nurses frequently, was found to be blue and not breathing. Suctioning of mucus and artificial respiration with oxygen by nasal catheter were carried out by the nurse and doctors who responded to an emergency call. At that time the heart rate was 50 per minute. After a few minutes the baby started to breathe, with gasping respirations, and the color improved. The heart rate likewise improved. Though the chest did not appear fully expanded, auscultation indicated satisfactory aeration. During the next few hours the baby did fairly well with nasal oxygen, but the respirations remained somewhat irregular, with intervals of apnea. A second episode of respiratory standstill and cyanosis occurred approximately six hours later. During the next two days the baby was kept in oxygen in an incubator. The color was fair, but the respirations continued irregular at times. The heart sounds were of good quality. The lungs were clear. The fontanelle was not full. There were no convulsions. Feedings were attempted, but the baby did not swallow and gavage feedings were instituted. The baby expired on the fourth day of life.

##### DIFFERENTIAL DIAGNOSIS

DR RALPH A ROSS In consideration of a problem such as this, we are faced with two large groups of malformations or diseases: congenital malformations and those due to trauma during or preceding delivery or to chemical trauma from oversedation. Also, I think that we should mention, particularly because of the history of previous neonatal death in the family, transplacental sensitization producing erythroblastosis, and such esoteric infections as toxoplasmosis, which might appear during the first two or three days of life. However, there is no evidence in the subsequent course to suggest such conditions.

There are many congenital lesions that might be considered. There is a possibility of respiratory obstruction due to a lesion in the respiratory tract, such as tracheoesophageal fistula. The fact that the baby could be gavage fed with ease, rules out that possibility. A diaphragmatic hernia could

have caused the repeated spells of cyanosis. We have no evidence, however, to support that diagnosis. Cardiovascular anomalies, particularly severe lesions of the heart such as transposition of the great vessels, are frequently associated with an amazing degree of oxygenation of the peripheral blood over a period of days, and at post-mortem examination it is impossible to understand how the baby could have survived at all. We have, however, no way of determining the possibility of congenital cardiac lesions from the information at hand.

Trauma due possibly to oversedation with one of the narcotics or large doses of barbiturates, heavy intoxication with depression of the baby's centers can be a cause of this picture. However, the evidence given does not indicate that cause. Gross trauma due to the forces of labor or to the force exerted during delivery may cause hemorrhage into the subarachnoid or subdural space or from the venous sinuses subtentorially. Usually they are associated with more dramatic signs and a different course, and signs of increased intracranial pressure are commonly found. Asphyxia due to interference with the blood supply during the force of labor, because of placenta praevia, premature separation of the placenta, of which we have no evidence in this case, or pressure on the cord interfering with the baby's blood supply may very well be the cause of severe damage to the general system, with resulting petechial hemorrhages throughout many organs of the body. The brain substance itself, being more susceptible to anoxic injury, is the organ that shows most symptoms. This is borne out in the present case by the abolition of the swallowing reflex. Aspiration of amniotic fluid or mucus may be due to asphyxia, it may occur in the course of labor, and may be the cause of respiratory obstruction following delivery. Atelectasis of the lungs may be due to obstruction of the bronchioles or to inability of the baby to institute adequate respiratory motions. I think it is accepted that atelectasis is secondary, not primary, in a case of cyanosis. In the present case we have the evidence of the cord about the neck, with sufficient pressure on it to produce cyanosis of the superficial skin of the head at birth, without any cyanosis below the pressure point around the neck. We have evidence of general involvement of the central nervous system, with irregular respirations, the inability to take food and the abolition of the swallowing reflex. There were no

signs or evidence of any increased intracranial pressure. We have no laboratory data to help us, owing to the fact, I assume, that the infant's condition was so precarious that any such measures as x-ray study of the chest or examination of the spinal fluid were contraindicated by that condition.

My diagnoses, therefore, are asphyxia, with diffuse petechial hemorrhages, atelectasis secondary to those, and probably some aspiration pneumonia.

#### CLINICAL DIAGNOSES

Asphyxia  
Cerebral hemorrhage, multiple

#### DR. ROSS'S DIAGNOSES

Asphyxia  
Diffuse petechial hemorrhage in brain substance.  
Atelectasis

#### ANATOMICAL DIAGNOSES

*Aspiration of amniotic fluid, massive  
Thrombosis of superior longitudinal sinus*

#### PATHOLOGICAL DISCUSSION

DR. CHARLES S. KUBIK. I shall tell you about the findings in the brain, and Dr. Sniffen will give you the other findings. There was a thrombus in the posterior part of the superior longitudinal sinus. Some of the cerebral veins entering the sinus on the right side were greatly distended, whereas those on the left were not, and it was thought that these engorged veins were also thrombosed. There was considerable hemorrhagic extravasation in the dura and falx in the region of the superior longitudinal sinus. There were no hemorrhages within the substance of the brain or the brain stem, which on gross examination were not definitely abnormal.

We have microscopical sections of practically all parts of the brain, the brain stem and the cerebellum. It is very difficult to tell even now whether the superior longitudinal sinus and veins in question contained ante-mortem thrombi or post-mortem clots. We thought that they were probably thrombi, though very recent ones, with no reaction of the intima or the adjacent hemorrhagic dura, and certainly less than four or even two days old. It is, therefore, unlikely that these findings account to any large extent for the symptoms that were observed. The brain, mid-brain, pons and medulla were not remarkable.

DR ALLAN M BUTLER That means that microscopically you found no evidence of anoxia of the brain cells?

DR KUBIK Nothing that seemed significant.

DR BUTLER No evidence of petechial hemorrhage?

DR KUBIK Certainly nothing striking. Small hemorrhages within the substance of the brain are not at all uncommon as a terminal event in cases in which there has been serious respiratory difficulty.

DR ROSS The episodes of cyanosis that were observed after birth may have been sufficient to cause some degree of petechial hemorrhage.

DR KUBIK They may have. Anoxia may be of a degree to cause severe disturbance of cerebral function without producing any characteristic histopathological changes. Perhaps Dr Sniffen can throw further light on the situation.

DR RONALD C SNIFFEN The gross findings in the viscera were unimpressive. There was obvious collapse of both lungs, and the liver was slightly pale. Microscopically, there proved to be a serious change in the lungs in the form of massive inhalation of amniotic fluid, which was identified by the presence of the cells of the vernix caseosa. The fluid had reached and obstructed the respiratory bronchioles and sometimes the alveolar ducts and consequently the alveoli were not aerated. A hyaline membrane lined many of the bronchioles. The formation of the hyaline membrane is presumed to have been the result of exaggerated respiratory effort with margination of the protein precipitate within the air ducts. The liver showed quite marked fatty change, and there was a nephrosis that involved the proximal convoluted tubules. Both these changes are seen in anoxia.

DR KUBIK Would the changes in the lung account for the difficulty in respiration?

DR SNIFFEN I should think so. There was a massive aspiration, with unexpanded lung beyond the obstruction.

DR BUTLER I should think that the findings suggest clearly that the baby had intrauterine anoxia with accentuation of respirations and an undue aspiration of amniotic fluid and later on suffered further anoxia due to faulty functioning of the respiratory center as a result of the first intrauterine anoxia.

DR KUBIK I might say that it is difficult to evaluate recent nerve-cell changes in infants. Judged by standards that apply in adults the cells look diseased in almost every case. In this case it may be said that there was no actual loss of nerve cells and no findings that would justify a diagnosis of anoxia. That would have to be made on the basis of the clinical manifestations.

DR BUTLER How long is the period before such changes result in necrosis?

DR KUBIK In localized lesions resulting from arterial occlusion in adults there are well defined and distinct changes within fifteen hours and probably less. They would be more difficult to recognize in a diffuse process and against a background of terminal changes.

DR ROSS Why should the infant have had loss of swallowing reflex? The post-mortem findings do not explain it.

DR KUBIK There may be serious derangement of function in a nervous structure that cannot be recognized histologically.

DR BUTLER The baby's respirations were typical of the respiration that results from anoxic damage to the respiratory center.

DR KUBIK In our experience with human beings changes that we can recognize do not occur unless there has been loss of consciousness. Even then remarkably little may be found in some cases. In a case of carbon monoxide poisoning the patient had been unconscious for a number of hours and then lived for several days, finally dying of a pulmonary embolus. There were two small patches of degeneration, and nothing definitely abnormal in the rest of the brain.

## THE LABORER AND HIS HIRE

THE task that faces the organized profession of medicine, the hospitals, hospital and medical service organizations and Government itself in determining the destiny of medical care constitutes one of the uppermost problems of the day. So great a cloud of witnesses is involved in any discussion of the problem that it is difficult to see clearly the issues involved and place them in their proper relation to one another.

Perhaps not of paramount importance but nevertheless particularly vexing have been the difficulties encountered as a result of Blue Cross payment of certain professional services rendered within hospitals and the relation between hospitals and staff physicians in certain branches of medicine. The

criticism has been made by these staff physicians, — anesthesiologists, pathologists and roentgenologists in particular, — who may be on full-time or part-time salaries, that employing hospitals have made a profit on their salaries and that Blue Cross, by arbitrarily including their services in its coverage, has classified the product of their training and experience as a hospital rather than a professional service.

They have thus been classed, it appears from their contention, with the clerks of a store or the employees of an industry from whose earnings a legitimate profit might be expected.

In an attempt to evaluate any grievance that any party may have, the purposes of professional organization should be clearly defined. It may be assumed that the first object of all medical organization is to provide the patient with the best possible care. A second legitimate object is to assure for the physician a decent and dignified standing in his community and a living commensurate with his ability and its industrious employment.

It is admitted that Blue Cross has blundered, it is apparent also that some hospitals have erred in failing to establish proper relations between staff and administration. The mistake is common when businessmen, occupied chiefly with balance sheets, have jurisdiction over institutions that are staffed by professional men jealous of the ethics and etiquette of their profession. Even the physician turned director is too often found, at least in the eyes of his former colleagues, worshipping the golden calf instead of heeding the commandments written in stone.

A committee was appointed by the Council of the Massachusetts Medical Society in the spring of 1947 "to define hospital services and medical services and to establish the proper relations between physicians and hospitals." This committee, composed of representatives of the anesthesiologists, the pathologists and the roentgenologists, the Blue Cross, the Blue Shield, the Hospital Association and the Massachusetts Medical Society, labored long and faithfully during the hot and humid summer that ensued. It brought in a unanimous report that has so far been unimpeachable and that defined as medical hospital services those "other than ad-

ministrative, rendered by a registered physician directly to or in behalf of an individual patient for the obtaining and interpretation of data, including consultation and advice, for the diagnosis, treatment and prevention of disease."

These services, specifically, were defined as embracing "the general and special practice of medicine, surgery and obstetrics, and the practice of the related specialties including anesthesiology, physical medicine, radiology, pathology and clinical pathology."

A basic principle recommended in the report was that each department (so far as possible) be self-supporting and that *neither the hospital nor the physician rendering the service should exploit the patient or each other*. The basis of financial arrangement, however, might be salary, commission, fees or any other method that would best meet the local situation.

Certain questions are not easily answered. Is a nurse anesthetist, operating under a doctor's orders, acting as his agent in a nurse's capacity or is she engaged in the practice of medicine? The point is open to debate. May a chemist, conducting his own clinical laboratory, perform an analysis and report the result to the physician submitting the material, if he does not presume to make a diagnosis? The organized pathologists believe not, but here, again, there is room for disagreement.

So long as organized medicine uses its organization for the benefit of the patient and the improvement of its own standards and public relations, well and good. If, however, its collective power should be used, as could easily happen, to protect its members against reasonable, honest and decent competition even from without the profession, it is treading dangerously close to the less attractive paths of trade unionism.

If the profession of medicine, blinded by its cloud of witnesses, closes its eyes to the fact that there are at least two reasonable sides to nearly any argument, it is simply blocking the very progress within its ranks that it is most desirous of promoting.

*Status quo* is but the eye of the hurricane and cannot prevail for long. Change is inherent in all human undertakings. The wrong of today may be the right of tomorrow. When the people of a nation have had

their minds made up, either by themselves or by some accepted agency they usually get eventually what they want or what they have been persuaded to think they want.

---

## ARMY MEDICAL RESEARCH

WAR is no longer characterized by small battles between professional armies for limited objectives. Whole populations are now involved, and the stake is nothing less than national survival. Indeed, the survival of a civilization may well be at stake in some future conflict. This broader concept of war vastly increases the responsibilities of the physician. It will no longer be enough for him to relieve the fighting troops of their sick and wounded or give medical care to the civilian population. He must do these things in time of war by all existing means, but in time of peace he must work to improve known methods and to discover methods never known before.

A recent address by Lieutenant Colonel Alfred P. Thom, M.C., chief of the Army Medical Research and Development Board, throws further light on this subject. It is good to know that the medical departments of the armed forces are keenly aware of the importance of basic research in the production of discoveries leading to major scientific advances, without which applied research alone would often be sterile. To give an idea of what the medical man is up against, a few of the most urgent problems are cited as examples: development of new physical and mental standards for the most efficient use of manpower, development of principles and psychiatric techniques to prevent psychiatric casualties in war, prevention and care of casualties due to or complicated by radiation sickness and radiation burns, cold-weather operations, including preselection of personnel for Arctic service, prevention and treatment of injuries due to cold and evacuation aspects of Arctic warfare, bacterial warfare—discovery and development of defensive measures against all known and suspected disease agents, and improvements in traumatic surgery, in control of common disabling diseases, in antibiotics and in techniques of immunization.

When it is remembered that a future war may make no distinction between combatants and non-combatants, the figures for the Army in the last war will give an idea of what the magnitude of the medical problem may be. Between January 1, 1942, and August 31, 1945, approximately 17,000,000 men were hospitalized, and 773,000 more men were required, directly or indirectly, to give them medical care. Thus with 10,000,000 men mobilized, at least 1 out of 10 was out of action each day either as a patient or as required for patient care. This was with the best health, disease and injury treatment record of any army in history. It is anticipated that, with widespread use of atomic and other new weapons in a future war, a much greater proportion of personnel and resources will have to be used for patient care, and the proportion of sick and injured may be much higher. How much higher the actual figure could be is suggested by the present population figure of 145,000,000. One other figure — also in the millions — is of immediate interest, and that is the annual budget of the Army Medical Research Program. It is just over \$3,000,000.

Colonel Thom's closing words need no comment or elaboration.

Every medical graduate should make it his business to be acquainted with the significance of sickness and injury in military campaigns and their possible influence on national survival, so that, if medical risks are taken, the advice given to those responsible for leadership will be such that the odds are carefully considered to give the best chances for success. In total war as never before experienced in the past, a superior, progressive army medical service and staff are fundamental requirements for winning a war. The effect on morale of inadequate care of sick and injured, as well as losses in manpower due to these causes, may be catastrophic. No citizen with medical training can consider himself a disinterested onlooker in medical problems involved in national defense. Your city may be the one chosen as a military target. We must have a superior, integrated, civil and armed force medical service if the nation is to survive. Every medical graduate must actively participate in this service and do his or her part.

## NEW ENGLAND DOCTOR AND HIS PUBLIC

THE Council of the New England State Medical Societies continues to perform one of its most important functions. Organized in 1945 "to bring about a closer co-operation between the State Medical societies in New England in the develop-

ment and maintenance of the highest standards in the conduct and administration of medicine, and in the furtherance of plans to improve the health of all the people in the New England States," it has added to this purpose the establishment of sound relations between the medical profession and the public.

On Sunday, March 7, 1948, despite winter and bad weather, approximately seventy-five Council members and other interested persons gathered at the Copley Plaza Hotel to engage in a discussion on *The New England Doctor and His Public*. Most of those present being physicians, "not snow nor rain . . . nor gloom of night" stayed them from the completion of this particular appointment.

Dr. Arthur H. Ruggles, of Providence, president of the Council, presided. Talks were given on the value of radio as a public-relations agency by James S. Powers, director of the Yankee Network Institute, on the doctor and his medical society as sources of news by Maurice Cronan, city editor of the *Hartford Courant*, and Gerald E. McLaughlin, managing editor of the *Rutland, Vermont, Daily Herald*, and on the doctor's role in community programs by Dr. Hugh R. Leavell, professor of public-health practice at Harvard University School of Public Health. These addresses were discussed by Dr. John F. Conlin, director of medical information and education of the Massachusetts Medical Society, James G. Burch, director of public relations of the Connecticut State Medical Society, and Dr. Robert O. Blood, former governor of New Hampshire.

The relations between the medical profession and the news-dispensing agencies are at present and have always been poor. The doctors, according to Mr. Powers, still dwell in their ivory tower of seclusion, still maintaining a public-be-damned attitude so far as the divulging of any news is concerned. This opinion was concurred in by the newspaper editors on the program, although definite signs of improvement are making themselves manifest — such as the very meeting at which these sentiments were expressed.

It is time for the mystery and magic in medicine to be finally and completely abolished. The public should be given the opportunity of learning about

medicine all that it can assimilate within the limits of its nonmedical education. The recent controversy over the Nolen-Miles Pound Bill has shown how sadly this information has been lacking.

At the same time the press and its public must realize that many of the confidences reposed in the doctor are in the nature of privileged communications and that he is in honor bound to respect them. They must realize that matters having to do with health and disease must be reported faithfully and interpreted accurately, and must be freed from sensationalism.

If the doctor is slow to expose himself to reprobation it is because he has sometimes been burned by it. There is no question that his public relations need improving, but the improvement must be on a mutual basis.

## PEDIATRICS

A RECRUIT is welcomed into the swelling ranks of medical journalism with the appearance of *Pediatrics*, the new official organ of the American Academy of Pediatrics. *Pediatrics*, as a journal owned by the Academy, replaces in its relation to that society *The Journal of Pediatrics* that had been published in the interest of the Academy under the proprietorship of the C. V. Mosby Company. The latter journal continues its independent course, with Dr. Borden S. Veeder, of St. Louis as editor.

The new journal, the first issue of which appeared in January, 1948, is edited for the Academy by Dr. Hugh McCulloch, of St. Louis, and a representative board of well known pediatricians. The first issue contains a Salute by Dr. Allan M. Butler, of Boston, the presidential address, given in December, 1947, by Dr. Lee Forrest Hill at the annual meeting of the American Academy of Pediatrics in Dallas, Texas, and a variety of scientific and clinical articles. A useful addition to the usual method of publication of papers is a summary of each in Spanish.

## MASSACHUSETTS MEDICAL SOCIETY

### DEATHS

**HAUPTMANN**—Alfred Hauptmann, M.D. of Newton Center, died on April 5. He was in his sixty-seventh year.

Dr. Hauptmann received his degree from Universität Heidelberg Medizinische Fakultät, Baden, in 1905. He came to the United States in 1939. He was a member of the staff of the Boston Dispensary, Joseph H. Pratt Diagnostic Hospital, and was medical director of the Bosworth Hospital.

His widow and a daughter survive.

**SCHULTZ**—Philip E. Schultz, M.D. of West Newton died on April 3. He was in his thirty-eighth year.

Dr. Schultz received his degree from Creighton University School of Medicine, Omaha, Nebraska, in 1933. He was a member of the American Society of Anesthetists Incorporated.

His widow survives.

## NEW HAMPSHIRE MEDICAL SOCIETY

### DEATHS

**LADD**—Samuel T. Ladd, M.D., of Portsmouth died on March 27. He was in his seventy-second year.

Dr. Ladd received his degree from Dartmouth Medical School in 1900. He was a former president of the New Hampshire Medical Society and was a member of the New Hampshire Surgical Society.

Three sons survive.

**RIECHMOND**—Allen P. Richmond, M.D. of Hingham died on March 17. He was in his eighty-eighth year.

Dr. Richmond received his degree from Bellevue Hospital Medical College in 1889. He was a life member of the New Hampshire Medical Society.

A son and two daughters survive.

## MEDICOLEGAL ABSTRACT

**Hospitals**—Standard of care required in the operation of the hospital pharmacy. The conduct of the modern hospital requires the operation of many related activities in connection with the hospitalization of patients. Interesting questions arise regarding the standard of care in the operation, supervision and maintenance of such activities as pharmacies, cafeterias, x-ray rooms, orthopedic gymnasiums and special appliance shops. One case that sometimes arises is the accidental substitution of a dangerous medication for a similar appearing but harmless drug. A recent Connecticut case involved such a problem.

A hospital maintained a pharmacy in the basement consisting of a workroom and a separate supply room. Boric acid and dextrose, which look alike, were purchased from the same concern in containers of similar cylindrical size and shape. A cylinder of each was kept on the floor of the pharmacy proper separated from each other by about four feet. The only distinguishing marks on the cylinders were the names of the medications and the additional words in small type on the boric acid container "for ex-

ternal use only" Boric acid is a poison and may be fatal to newborn babies if taken internally

Under hospital routine newborn infants were given a feeding of 5 per cent dextrose solution. On this occasion the maternity ward sent the dextrose bottle to the pharmacy to be refilled, and it was filled with boric acid, whose use in the formula resulted in the death of five babies and in injuries to a sixth. Since the hospital employed a registered pharmacist and there was apparently no negligence in his selection, it was not liable for any negligence of the pharmacist under the charitable immunity rule that prevails in Connecticut. The plaintiff, the administrator of the estate of one of the deceased babies, sought to recover, therefore, on the grounds that the hospital itself was negligent in failing to provide proper facilities, safeguards and surroundings in the pharmacy. The hospital, on the other hand, argued that it had established its pharmacy in accordance with standard practice, so that if there were any negligence involved in this respect, it was negligence on the part of the pharmacist to whom the hospital had properly delegated the job of running the pharmacy. The issue, therefore, was not whether the pharmacist or some other employee was negligent in using the wrong bottle, but whether the use of the wrong bottle resulted from a violation by the hospital management itself of a duty, which it could not delegate to subordinates, to provide certain safeguards against such mistakes in the operation of its pharmacy.

The trial court instructed the jury that certain duties were duties of the hospital and could not be delegated. In describing the extent of these non-delegable duties, the trial court said

This includes the duty to make provision for the inspection and use of all drugs, food, equipment, and appliances, and the report of anything unusual, uncommon or serious if, and insofar as, and to the extent that you find the making of such provision is involved in its corporate function of exercising reasonable care, in view of the functions of the hospital, and the dangers reasonably to be anticipated in their performance.

The jury returned a verdict for the plaintiff, but on appeal it was set aside and a new trial ordered. The judge's instruction to the jury was described as "entirely too broad a statement because it made the most trivial duties in connection with the running of the hospital non-delegable and possible bases of liability. If applied, it would practically eliminate the doctrine of charitable immunity of a hospital."

The court further stated

The trial court should not have submitted the question whether defendant failed to provide proper facilities and safeguards in the pharmacy to the jury. All of the evidence was to the effect that the pharmacy was set up in accordance with standard practice, and there was no evidence to the contrary. No written rules for its conduct had been prescribed, and there was no evidence that standard practice required this or that their existence would have changed the situation. The motion to set aside the verdict should have been granted.

In view of this conclusion, there is little in the appeal from the judgment which requires mention. The foregoing discussion negatives the claim of the defendant that charitable immunity protects a hospital even against true corporate negligence.

True corporate negligence has been defined by the Connecticut court in another case (*Evans v. Lawrence and Memorial Hospitals*, 50 Atl. 2d 443, 1946) as negligence on the part of the board of trustees acting as a board, or on the part of the executive committee of the hospital acting as such a committee within the scope of its authority. Such negligence ordinarily is in the selection of doctors, servants or employees and is a basis for liability in a number of states besides Connecticut.

This decision turns on the extent of the doctrine of charitable immunity in the particular state. In Massachusetts, on similar facts in the case of *Roosen v. Peter Bent Brigham Hospital* (235 Mass. 66) the substitution of corrosive sublimate for epsom salts—drugs that closely resemble each other and were kept in near proximity to each other in the pharmacy—and on an action to hold the hospital for corporate negligence in the selection of servants, the court stated

If a hospital is to be held responsible for negligent treatment of patients, there seems to us to be no sound ground for distinction between the negligence of the managers of the hospital and the negligence of subordinate servants as a basis for liability. A sound ground for distinction between exoneration from liability for the negligence of managers and that of subordinate servants seems equally wanting. Since it is settled that there is no liability for negligence of the latter, it must follow that there is none for that of the former. The inevitable result of our own decisions is to relieve a hospital from liability for negligence of the managers in selecting incompetent subordinate agents, as well as for the negligence of such subordinate agents selected with care.

## MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

### CONSULTATION CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS

The May schedule for Consultation Clinics for Crippled Children in Massachusetts under the provisions of the Social Security Act follows

CLINIC	DATE	CLINIC CONSULTANT
Salem	May 3	Paul W. Hugenberger
Lowell	May 7	Albert H. Brewster
Gardner	May 11	Carter R. Rowe
Haverhill	May 12	William T. Green
Brockton	May 13	George W. Van Gorder
Springfield	May 18	Garry deN. Hough, Jr.
Pittsfield	May 19	Frank A. Slowick
Worcester	May 21	John W. O'Meara
Fall River	May 24	David S. Grice
Hyannis	May 27	Paul L. Norton

Physicians referring new patients to clinics should get in touch with the district health officer to make appointments. Patients are seen by appointment only.

## MISCELLANY

## BOSTON CITY HOSPITAL ALUMNI ASSOCIATION

The Boston City Hospital Alumni Association held its sixteenth annual reunion and dinner at the Harvard Club of Boston on April 24.

The conspicuous event of the evening was the presentation of the newly established Major General Leonard Wood award to Dr. Elliott P. Joslin. This award will be given to distinguished members of the Association who have achieved fame in medicine or surgery.

## CORRESPONDENCE

## RESTORATION OF LICENSE

To the Editor: At the meeting of the Board of Registration in Medicine held April 8, it was voted to restore the registration to practice medicine in this Commonwealth to Dr. Mary E. Bolger formerly of Worcester.

H. QUINBY GALLUPE, M.D. Secretary  
Board of Registration in Medicine

State House  
Boston

## SERUM JAUNDICE

To the Editor: In the March 25 issue of the *Journal*, under the heading of Idiopathic Hyperlipemia Hopgood cited the history of a twenty six year-old man with this condition. The patient was first admitted to the hospital on December 11, 1946 when various tests were performed among them being blood chemical determinations. He was discharged and was readmitted two months later for further study, but immediately started to run the classic course of hepatitis. The author states that the jaundice is believed to have been a simple infectious hepatitis.

The course of events that occurred in the case reported has subsequently been repeated many times. In the past year or two it has been increasingly distressing on acute ward services where many venipunctures or injections are given, to have the patients return in two or three months with hepatitis. Although no blood or blood products are administered in these cases their incubation periods justify their inclusion in the category of homologous serum jaundice. The virus is transmitted from an asymptomatic carrier or an active case to the hospital patient under investigation by the agency of improperly cleaned syringes or needles. A drop of serum remaining in a syringe is all that is necessary to infect a new victim. Because of this situation every puncture of a patient's skin whether for blood sugar, white-cell count or to introduce penicillin poses a potential threat to an already sick person unless certain precautions are taken.

Individual syringes and needles should be used whenever practicable. Certainly in cases of infectious hepatitis this is most desirable. If this measure cannot be carried out, all syringes should be thoroughly washed and needles sterilized and rinsed. For the time being autoclaving remains the preferred method of sterilization.

These precautions are simple and well worth the trouble in view of the increasing incidence of "hospital hepatitis".

ternal use only" Boric acid is a poison and may be fatal to newborn babies if taken internally

Under hospital routine newborn infants were given a feeding of 5 per cent dextrose solution. On this occasion the maternity ward sent the dextrose bottle to the pharmacy to be refilled, and it was filled with boric acid, whose use in the formula resulted in the death of five babies and in injuries to a sixth. Since the hospital employed a registered pharmacist and there was apparently no negligence in his selection, it was not liable for any negligence of the pharmacist under the charitable immunity rule that prevails in Connecticut. The plaintiff, the administrator of the estate of one of the deceased babies, sought to recover, therefore, on the grounds that the hospital itself was negligent in failing to provide proper facilities, safeguards and surroundings in the pharmacy. The hospital, on the other hand, argued that it had established its pharmacy in accordance with standard practice, so that if there were any negligence involved in this respect, it was negligence on the part of the pharmacist to whom the hospital had properly delegated the job of running the pharmacy. The issue, therefore, was not whether the pharmacist or some other employee was negligent in using the wrong bottle, but whether the use of the wrong bottle resulted from a violation by the hospital management itself of a duty, which it could not delegate to subordinates, to provide certain safeguards against such mistakes in the operation of its pharmacy.

The trial court instructed the jury that certain duties were duties of the hospital and could not be delegated. In describing the extent of these non-delegable duties, the trial court said:

This includes the duty to make provision for the inspection and use of all drugs, food, equipment, and appliances, and the report of anything unusual, uncommon or serious if, and insofar as, and to the extent that you find the making of such provision is involved in its corporate function of exercising reasonable care, in view of the functions of the hospital, and the dangers reasonably to be anticipated in their performance.

The jury returned a verdict for the plaintiff, but on appeal it was set aside and a new trial ordered. The judge's instruction to the jury was described as "entirely too broad a statement because it made the most trivial duties in connection with the running of the hospital non-delegable and possible bases of liability. If applied, it would practically eliminate the doctrine of charitable immunity of a hospital."

The court further stated:

The trial court should not have submitted the question whether defendant failed to provide proper facilities and safeguards in the pharmacy to the jury. All of the evidence was to the effect that the pharmacy was set up in accordance with standard practice, and there was no evidence to the contrary. No written rules for its conduct had been prescribed, and there was no evidence that standard practice required this or that their existence would have changed the situation. The motion to set aside the verdict should have been granted.

In view of this conclusion, there is little in the appeal from the judgment which requires mention. The foregoing discussion negatives the claim of the defendant that charitable immunity protects a hospital even against true corporate negligence.

True corporate negligence has been defined by the Connecticut court in another case (*Ernst v. Lawrence and Memorial Hospitals*, 50 Atl. 2d 443, 1946) as negligence on the part of the board of trustees acting as a board, or on the part of the executive committee of the hospital acting as such a committee within the scope of its authority. Such negligence ordinarily is in the selection of doctors, servants or employees and is a basis for liability in a number of states besides Connecticut.

This decision turns on the extent of the doctrine of charitable immunity in the particular state. In Massachusetts, on similar facts in the case of *Roosen v. Peter Bent Brigham Hospital* (235 Mass. 66) the substitution of corrosive sublimate for epsom salts—drugs that closely resemble each other and were kept in near proximity to each other in the pharmacy—and on an action to hold the hospital for corporate negligence in the selection of servants, the court stated:

If a hospital is to be held responsible for negligent treatment of patients, there seems to us to be no sound ground for distinction between the negligence of the managers of the hospital and the negligence of subordinate servants as a basis for liability. A sound ground for distinction between exoneration from liability for the negligence of managers and that of subordinate servants seems equally wanting. Since it is settled that there is no liability for negligence of the latter, it must follow that there is none for that of the former. The inevitable result of our own decisions is to relieve a hospital from liability for negligence of the managers in selecting incompetent subordinate agents, as well as for the negligence of such subordinate agents selected with care.

## MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

### CONSULTATION CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS

The May schedule for Consultation Clinics for Crippled Children in Massachusetts under the provisions of the Social Security Act follows:

CLINIC	DATE	CLINIC CONSULTANT
Salem	May 3	Paul W. Hugenberger
Lowell	May 7	Albert H. Brewster
Gardner	May 11	Carter R. Rowe
Haverhill	May 12	William T. Green
Brockton	May 13	George W. Van Gorder
Springfield	May 18	Garry deN. Hough, Jr.
Pittsfield	May 19	Frank A. Slowick
Worcester	May 21	John W. O'Meara
Fall River	May 24	David S. Gnee
Hyannis	May 27	Paul L. Norton

Physicians referring new patients to clinics should get in touch with the district health officer to make appointments. Patients are seen by appointment only.

# MISCELLANY

## BOSTON CITY HOSPITAL ALUMNI ASSOCIATION

The Boston City Hospital Alumni Association held its sixteenth annual reunion and dinner at the Harvard Club of Boston on April 24.

The conspicuous event of the evening was the presentation of the newly established Major General Leonard Wood award to Dr Elliott P Joslin. This award will be given to distinguished members of the Association who have achieved fame in medicine or surgery.

# CORRESPONDENCE

## RESTORATION OF LICENSE

To the Editor: At the meeting of the Board of Registration in Medicine held April 8 it was voted to restore the registration to practice medicine in this Commonwealth to Dr Mary E. Bolger, formerly of Worcester.

H QUIMBY GALLUPE, M.D. Secretary  
Board of Registration in Medicine.

State House  
Boston

## SERUM JAUNDICE

To the Editor: In the March 25 issue of the *Journal* under the heading of "Idiopathic Hyperlipemia" Hopgood cited the history of a twenty-six year-old man with this condition. The patient was first admitted to the hospital on December 11, 1946 when various tests were performed among them being blood chemical determinations. He was discharged and was readmitted two months later for further study, but immediately started to run the classic course of hepatitis. The author states that the jaundice is believed to have been a simple infectious hepatitis.

The course of events that occurred in the case reported has subsequently been repeated many times. In the past year or two it has been increasingly distressing on active ward services where many venepunctures or injections are given, to have the patients return in two or three months with hepatitis. Although no blood or blood products are administered in these cases their incubation periods justify their inclusion in the category of homologous serum jaundice. The virus is transmitted from an asymptomatic carrier or an active case to the hospital patient under investigation by the agency of improperly cleaned syringes or needles. A drop of serum remaining in a syringe is all that is necessary to infect a new victim. Because of this situation every puncture of a patient's skin, whether for blood sugar, white-cell count or to introduce penicillin poses a potential threat to an already sick person unless certain precautions are taken.

Individual syringes and needles should be used whenever practicable certainly, in cases of infectious hepatitis this is most desirable. If this measure cannot be carried out, all syringes should be thoroughly washed and needles sterilized and rinsed. For the time being autoclaving remains the preferred method of sterilization.

These precautions are simple and well worth the trouble in view of the increasing incidence of hospital hepatitis.

MARTIN C ROSENTHAL, M.D.

115 Central Park West, New York 23 New York

## Postgraduate Division

PRINCIPLES OF SURGICAL TECHNIQUE June 1 - July 10

Candidates must have had previous surgical training and experience. Laboratory work consisting of operations upon animals, is supplemented by lectures and illustrated demonstrations. Drs C Stuart Welch and Lewis S. Pilcher in charge. Tuition fee \$200. Enrollment limited to 30.

### Courses for the General Practitioner

RADIOLOGY May 12-14. A three-day full-time course in chest x-ray including roentgenologic interpretations of the heart and lungs in health and disease. Dr Alice Ettinger in charge. Tuition fee \$25

OPHTHALMOLOGY June 2-23 Monday Wednesday and Friday mornings. The commoner external eye diseases and their treatment are taught through demonstration of patients. Instruction is given in the proper use of the ophthalmoscope with interpretations of the normal fundus and fundus lesions in relation to general medicine. Dr Joseph Iperheimer in charge. Tuition fee \$75. Enrollment limited to 5. Ophthalmoscope required.

PEDIATRICS, June 1-12 This is a two-week full-time course in which problems both physical and mental, are discussed and demonstrated by pediatricians specializing in specific aspects of childhood disturbances. Dr Irving Silverman in charge. Tuition fee \$75

All courses may be taken under the G. I. Bill of Rights

No Test Tubes No Measuring No Boiling

Diabetics welcome "Spot Tests" (ready to use dry reagents) because of the ease and simplicity in using. No test tubes, no boiling, no measuring, just a little powder, a little urine—color reaction occurs at once if sugar or acetone is present.

Galatest. Acetone Test (Denco)

FOR DETECTION OF SUGAR IN THE URINE

FOR DETECTION OF ACETONE IN THE URINE

SAME SIMPLE TECHNIQUE FOR BOTH

1. A LITTLE POWDER

2. A LITTLE URINE

COLOR REACTION IMMEDIATELY

A carrying case containing one vial of Acetone Test (Denco) and one vial of Galatest is now available. This is very convenient for the medical bag or for the diabetic patient. The case also contains a medicine dropper and a Galatest color chart. This handy kit or refills of Acetone Test (Denco) and Galatest are obtainable at all prescription pharmacies and surgical supply houses.

Accepted for advertising in the Journal of the A.M.A.  
 WRITE FOR DESCRIPTIVE LITERATURE

## INTERNATIONAL CONGRESSES ON TROPICAL MEDICINE AND MALARIA

The fourth International Congresses on Tropical Medicine and Malaria and the first to be held since 1938 will convene in Washington, D. C., from May 10 to 18. The Congresses will be held under the auspices of the Department of State, and of over sixty nations to which invitations have been extended, thirty-three have already accepted and will send official delegations.

## MEDICAL VETERANS OF WORLD WAR II

An organizational meeting of physicians who served in World War II will be held at the Boston Medical Library on Thursday, May 13, at 8 00 p. m. The purpose of the proposed organization is to form a democratic group of physicians for the advance and protection of the medical profession in general and of the physician-veteran in particular.

Such an organization is particularly appropriate at the present critical time, and every physician who is a veteran of the recent war is urged to attend. Please notify friends who may be eligible.

Further information may be obtained from Kenneth A. Brown, M.D., 442 Walnut Street, Newtonville (Telephone Bigelow 4-0394).

## CHILDREN'S HOSPITAL ALUMNI ASSOCIATION

The annual meeting and dinner of The Children's Hospital Alumni Association will be held at the Hotel Berconshild, Brookline, on Wednesday, June 2, at 6 30 p. m. A short business meeting will be held, but the evening will be devoted mainly to social activities. Mr. Bradford Washburn will show colored films on Alaska.

Before the meeting a clinicopathological conference will be held in the amphitheater of the Peter Bent Brigham Hospital from 12 00 m. to 1 00 p. m., and a clinical meeting and presentation of cases will be conducted in the amphitheater of The Children's Hospital from 2 00 to 4 30 p. m.

## LASKER AWARD

The 1948 Lasker Award of \$1000 for outstanding service in mental hygiene will be presented for a recent significant contribution to the education of the physician in the psychologic aspects of the practice of medicine (by "physician" is specified the nonpsychiatric medical practitioner), it was recently announced. The work of the candidates for the award must have been accomplished or generally accepted during the past year or two. Presentation of the award will be made at the annual meeting of the National Committee for Mental Hygiene on November 3 and 4 in New York City.

(Notices concluded on page xiii)

The ultimate success of the repair depends upon the observance of two important steps in the technic. In the first place, the hernia sac must be eliminated. This is accomplished in the majority of cases by means of a series of plicating sutures of silk placed in the free peritoneal portion of the sac in a circumferential direction (Fig 2B and 2C). Before this layer is inserted, it is often possible to free much of the sac from its attachment to the underlying wall of the stomach near the cardia. This serves to make plication of the sac easy, but is not essential to the success of the procedure. It is not necessary to open or to remove the sac in the average case.

In a few cases, however, it will be found that the enlargement of the peritoneal reflection that forms the major portion of the wall of the hernia sac has developed far beyond the extent of the stomach into the chest. In such cases a large redundant portion of the sac can be freed and removed. The base of this type of sac must, of course, be closed either by a suture ligature or by means of a series of mattress sutures. The remainder of the sac is then plicated in the usual way.

Occasionally, when the sac is a large one, it is necessary to insert two layers of plication sutures to maintain a reduction of the hernia. If the sac

put more of these sutures to the left than to the right (Fig 2D and 2E). One layer usually suffices, but two layers may be necessary if the diaphragm is unusually thick. It is unwise, however, to apply a second layer if it produces any tendency to roll the edge of the diaphragm up onto the esophagus, because of the danger of causing an angulation just above the gastric cardia. The repair can be given greater strength and permanency by the insertion

FIGURE 4. Diagram illustrating the method suggested in cases in which the enormous size of the hernia makes it difficult to maintain reduction while the repair is being carried out. The stomach and omentum have been pulled out through a counterincision in the diaphragm. After repair of the hernia has been completed the stomach and omentum will be replaced in the abdomen and the opening in the diaphragm closed.

FIGURE 3. A view of the left hemithorax before closure of the chest wall incision.

Suture of the opening in the mediastinal pleura is shown after completion of the repair.

has been properly inverted by plication or removed, the hernia remains reduced with the cardia at or just below the level of the hiatus (Fig 2C).

The second important step of the operation is to narrow the hiatus to such a size that the reduction of the hernia can be held permanently. This is accomplished by means of several sutures of heavy silk placed solidly through the muscle wall behind each edge of the hiatus. Because of the natural transverse direction of the opening in the majority of cases, these sutures must be placed at each side of the esophagus. It is usually necessary, because of the relation of the esophagus to the opening, to

of a reinforcing suture of fascia lata obtained by an assistant from the patient's left thigh.

In narrowing the hiatus of the diaphragm it is necessary to exert great care to avoid a constriction that might lead to delay in the passage of food through the esophagus at that level. A good rule to follow is that if the index finger of the surgeon can easily be inserted beside the esophagus, the correct size of the opening has been established. By adherence to this rule, postoperative dysphagia has been avoided in all cases.

To complete the operation, the mediastinal pleural incision is closed with fine-silk sutures, and the edges of the pleura reattached to the diaphragm near the hiatus (Fig 3). The lung is then expanded by the anesthetist, and the chest-wall incision is closed in the usual fashion, interrupted silk sutures being used.

#### DIFFICULTIES ENCOUNTERED

In certain cases in which the hernia is unusually large, consisting of almost the entire stomach, a large part of the transverse colon, the great omentum and sometimes a portion of the small intestine as well, it is impossible to maintain a state of reduction while the repair is being made. In some of these cases, as in certain enormous scrotal hernias,

case, but in the majority it is ovoid rather than round. This fact favors the placing of the sutures used to produce a narrowing of the opening. Also, in the majority of cases the direction of this ovoid enlargement of the hiatus is transverse or oblique

FIGURE 1 A Shows the Exposure of the Operative Field Obtained by Incision through the Left Hemithorax, Excising the Eighth Rib, and B Dissection of the Hernia, the Lower Esophagus and the Margins of the Esophageal Hiatus after Incision of the Mediastinal Pleura (Inset Direction of the Incision on the Chest Wall)

Rarely is it anteroposterior. This fact must likewise be borne in mind when sutures are being placed.

In rare cases there is a congenital absence of a portion of the diaphragm, which should normally make up a part of the margin of the hiatus. The correction of this condition presents technical difficulties that offer further opportunity to demonstrate the superiority of the thoracic approach. It is highly improbable that such a defect could be corrected through an abdominal incision.

#### DESCRIPTION OF THE OPERATION

With the patient lying on the right side and the left arm drawn up in front of his face, a long oblique incision is made across the left side of the chest in the direction of the ribs. Because of the fact that the majority of patients with hiatus hernia who require surgery are of middle age or older and therefore have an inflexible chest wall, it is better to resect a rib than to attempt to obtain sufficient exposure by an intercostal incision. Resection of the eighth rib gives the best results in the average case.

A rib spreader is inserted, and the lower lobe of the lung is retracted. The exposure obtained by this means is illustrated in Figure 1. The hernia sac and contents are easily identified lying beneath the pulmonary ligament and the pleural reflection over the lower mediastinum (Fig 1A).

The left phrenic nerve is crushed with a hemostatic forceps at the point where it leaves the surface of the pericardium to enter the diaphragm. The tranquility of the diaphragm thus induced not only assists in the performance of the operation itself but also, by ensuring temporary inactivity of the muscle, encourages firm healing of the structures that have been sutured. When the abdominal approach is used, this step must be performed through an incision in the neck, as Harrington<sup>1</sup> advocates.

The mediastinal pleura overlying the hernia is incised longitudinally and removed from its attachment around the margin of the hiatus. The hernia

FIGURE 2 A Is a Diagram Illustrating the Most Frequent Type of Hernia, with an Apparent Shortening of the Esophagus Brought about by the Upward Thrust of the Herniated Portion of the Stomach, the Sac Consisting of a Reduplication of Peritoneum over the Anterior Aspect of the Herniated Stomach. D and E Illustrate Placement of the Sutures Used to Narrow the Esophageal Hiatus.

sac, the herniated portion of stomach, the lower end of the esophagus and the overlying vagus nerves are freed by dissection. The margins of the hiatus are identified and cleared of the areolar tissues that are found attached to them (Fig 1B).

The ultimate success of the repair depends upon the observance of two important steps in the technic. In the first place, the hernia sac must be eliminated. This is accomplished in the majority of cases by means of a series of plication sutures of silk placed in the free peritoneal portion of the sac in a circumferential direction (Fig 2B and 2C). Before this layer is inserted, it is often possible to free much of the sac from its attachment to the underlying wall of the stomach near the cardia. This serves to make plication of the sac easy, but is not essential to the success of the procedure. It is not necessary to open or to remove the sac in the average case.

In a few cases, however, it will be found that the enlargement of the peritoneal reflection that forms the major portion of the wall of the hernia sac has developed far beyond the extent of the stomach into the chest. In such cases a large redundant portion of the sac can be freed and removed. The base of this type of sac must, of course, be closed either by a suture ligature or by means of a series of mattress sutures. The remainder of the sac is then plicated in the usual way.

Occasionally, when the sac is a large one, it is necessary to insert two layers of plication sutures to maintain a reduction of the hernia. If the sac

put more of these sutures to the left than to the right (Fig 2D and 2E). One layer usually suffices, but two layers may be necessary if the diaphragm is unusually thick. It is unwise, however, to apply a second layer if it produces any tendency to roll the edge of the diaphragm up onto the esophagus, because of the danger of causing an angulation just above the gastric cardia. The repair can be given greater strength and permanency by the insertion

FIGURE 4. Diagram illustrating the method suggested in cases in which the enormous size of the hernia makes it difficult to maintain reduction while the repair is being carried out. has been properly inverted by plication or removed, the hernia remains reduced with the cardia at or just below the level of the hiatus (Fig 2C).

The second important step of the operation is to narrow the hiatus to such a size that the reduction of the hernia can be held permanently. This is accomplished by means of several sutures of heavy silk placed solidly through the muscle wall behind each edge of the hiatus. Because of the natural transverse direction of the opening in the majority of cases, these sutures must be placed at each side of the esophagus. It is usually necessary, because of the relation of the esophagus to the opening, to

of a reinforcing suture of fascia lata obtained by an assistant from the patient's left thigh.

In narrowing the hiatus of the diaphragm it is necessary to exert great care to avoid a constriction that might lead to delay in the passage of food through the esophagus at that level. A good rule to follow is that if the index finger of the surgeon can easily be inserted beside the esophagus, the correct size of the opening has been established. By adherence to this rule, postoperative dysphagia has been avoided in all cases.

To complete the operation, the mediastinal pleural incision is closed with fine-silk sutures, and the edges of the pleura reattached to the diaphragm near the hiatus (Fig 3). The lung is then expanded by the anesthetist, and the chest-wall incision is closed in the usual fashion, interrupted silk sutures being used.

#### DIFFICULTIES ENCOUNTERED

In certain cases in which the hernia is unusually large, consisting of almost the entire stomach, a large part of the transverse colon, the great omentum and sometimes a portion of the small intestine as well, it is impossible to maintain a state of reduction while the repair is being made. In some of these cases, as in certain enormous scrotal hernias,

there seems to be insufficient room within the abdomen for the long-displaced viscera. To overcome this difficulty it is necessary only to make a short counterincision in the diaphragm well away from the hiatus. Through this incision the herniated viscera are easily pulled into the abdomen and if necessary out over the lower edge of the thoracic incision, where they are protected with a pad of wet gauze (Fig 4). The sac can then be dealt with, and

TABLE 1 *Indications for Operation in 51 Patients Operated upon for Hiatus Hernia*

the opening in the hiatus reduced to proper size with less difficulty than in the average case. After the repair of the hernia has been completed, the viscera are replaced in the abdomen and the incision in the diaphragm is closed. If the sutures used to close this incision tend to pull through the tissues because of the increased pressure within the abdomen, a strip of fascia lata will overcome the difficulty.

It sometimes happens, when sutures are placed across the hiatus to the right of the esophagus, that the branch of the right vagus nerve that passes to the celiac ganglion interferes. In such a case, this

branch of the nerve should be divided. No untoward result has been observed to follow this maneuver in the few cases in which it has been necessary.

If the esophagus is actually too short and a portion of the stomach is therefore congenitally thoracically placed, no attempt to change the situation should be made. Furthermore, it is not necessary in such cases to elevate the diaphragm in an attempt to relieve the patient. The pain is eliminated if the peritoneal sac is removed, after it has been dissected free from the stomach, or if it is thoroughly inverted below the level of the hiatus.

## POSTOPERATIVE CARE

The management of the early convalescence of the patient offers no special problems other than those likely to be encountered whenever a thoracotomy is performed. It is wise to leave a Levin tube in the stomach during the first forty-eight hours to prevent gastric dilatation. The patient should be fed with caution at first, but a normal diet is usually tolerated by the seventh or eighth day. Early ambulation is encouraged. The majority of patients are out of bed from the second day on. The average period of hospital stay after the operation is twelve and a quarter days.

## CLINICAL EXPERIENCE

The operation described above has been used in the treatment of 51 patients with hiatus hernia of the diaphragm. In every case an important indication for the operation existed. In the majority of cases the reason for operation was the occurrence of severe attacks of pain, which could not be con-

Not stated	3

trolled by dietary or medicinal means. In a few cases a severe degree of blood loss, usually of a chronic nature, provided the indication for surgery. In the remainder there was incarceration of the hernia, usually with obstruction, either intermittent or complete (Table 1).

Postoperative complications occurred in 5 patients (Table 2). One patient, whose operation was performed early in the series before penicillin was available, developed a localized empyema, which required drainage. Thrombophlebitis of the leg veins developed in 3 cases, in 1 of which a sublethal pulmonary embolism occurred. The only other complication consisted of minor, superficial wound infection, which was not serious enough to delay discharge from the hospital.

In a comparable series of 25 cases of hiatus hernia repaired at the Massachusetts General Hospital by other surgeons using the abdominal approach, there were complications in 7 cases and 1 postoperative fatality.

There were no postoperative deaths among the 51 patients operated upon transthoracically.

For the information of those who may hesitate to use the thoracic approach because of the fear that the incision may remain painful for a long period after the operation, a careful inquiry was made of

all the 43 patients whose operations were performed six months or more ago. A definite statement was obtained from 42 of these patients. In no case had there been any severe pain after the immediate postoperative period. Four of the patients reported slight discomfort, but 38 patients experienced no discomfort from the incision after the first few weeks (Table 3).

### RESULTS

Eight patients have been operated upon so recently that a follow-up study of the result would hardly be significant. The remaining 43 patients, however, were operated upon six months or more ago, and the results of a recent study of their present status are illustrated in Table 4. Criteria for evaluation of the end result in these cases have been based upon the statements of the patient and his physician regarding the relief of symptoms and, whenever possible, upon roentgenographic evidence obtained by the ingestion of barium. In none of these cases has a definite recurrence of the hernia been demonstrated by roentgen-ray studies. In 1 patient there is evidence still of a slight protrusion of the cardiac end of the stomach above the hiatus. In this case, however, the reduction of the herniated stomach was incomplete at operation because of an abnormally short esophagus. Furthermore, the patient, who was a chronic invalid because of the severity of the pain before operation, is now cured of the pain caused by the hernia. He continues to have occasional attacks of angina pectoris from known pre-existing coronary-artery disease. In another patient there is an equivocal shadow in a roentgen ray film obtained several months after operation. This case is classified as suggestive of recurrence although the symptoms were completely relieved by the operation.

The failure to relieve the discomfort in 1 case may mean that the symptoms were erroneously ascribed to the hernia. At any rate, no roentgen-ray evidence of recurrence has been observed in this patient. The same thing may be said for the 3 patients who are only partially relieved of discomfort. In all the other 39 patients, including those who had bled and those with an incarceration of the hernia, as well as those who had pain only, the relief of symptoms has been complete and permanent (Table 4).

Soutter<sup>2</sup> found after a review of 24 cases of hiatus hernia repaired through the abdomen at the Massachusetts General Hospital that a large number had apparently recurred, often before the patient left the hospital. In the 9 patients of this group who had subsequent investigation by roentgen-ray studies a definite recurrence was observed. On the other hand, of the 43 patients operated upon by the thoracic approach six months or more ago, 95.5

per cent show no suggestion or evidence of recurrence. This result, when compared with the results obtained by the use of the abdominal approach, at least among the cases observed at the Massachusetts General Hospital, demonstrates the superiority of the supradiaphragmatic operation.

### CONCLUSIONS

The widely prevalent belief among physicians and some surgeons that an operation for the repair of hiatus hernia of the diaphragm, especially when performed by the thoracic approach, is unusually dangerous or attended by a high incidence of complications is erroneous.

The widespread impression among physicians and surgeons that the repair of a hiatus hernia of the diaphragm is likely to be followed by a high incidence of recurrence is based upon experience with the abdominal approach and does not apply when the supradiaphragmatic operation is used.

# PROLONGED PAROXYSMAL AURICULAR TACHYCARDIA

## Report of a Case Including Treatment with Veratrum Viride

ERNEST W. SHAW, M.D.\*

BOSTON

THERE have been several reports in the literature of cases of prolonged paroxysmal auricular tachycardia. The case reported below is presented because it is somewhat rare and it is the first case in which veratrum viride has successfully though temporarily stopped an episode of tachycardia.

Peterman<sup>1</sup> reported a quite similar case in a six-year-old child who developed an auricular rate of 160 in November, 1943, and at the time of the study (January, 1946) the tachycardia had persisted. Digitalis was given until toxic effects were produced without stopping the tachycardia, mecholyl produced only temporary conversion to normal rhythm, and papaverine, ipecac, quinidine and intravenous magnesium sulfate were without effect. An inflated blood-pressure cuff about the neck caused an immediate conversion to normal sinus rhythm, but the paroxysmal auricular tachycardia returned the next day. There was no known cause of the tachycardia, though it was first noted after several very severe upper respiratory infections.

Mayer<sup>2</sup> described a case in a ten-year-old girl who had had a persistent tachycardia starting at the age of one. There was no known precipitating cause.

Piotti<sup>3</sup> reported a case in a child first observed at the age of eleven months in an episode lasting twenty-three days. A later attack lasted seven months. Various therapeutic agents were tried, including digitalis, quinidine and ergotamine tartrate, none of which had any effect. The patient finally died in congestive heart failure at the age of eighteen months. Histologic examination of the heart at autopsy revealed an interstitial myocarditis of the Fiedler type. The lesion was located only in the right auricle and in the region where the fibers of connection run from the ostium of the coronary sinus to the node of Aschoff-Tawara.

Mahaim<sup>4</sup> reported a case very similar to that of Piotti, in a fourteen-month-old child who developed the condition after a respiratory infection. The initial paroxysm lasted fifteen days and was followed by another during which the child died of bronchopneumonia. Post-mortem examination revealed some recent inflammatory lesions of the Keith-Flack node.

Cooke and White<sup>5</sup> reported an episode in an infant aged eighteen months that lasted over twelve months without any apparent ill effects. This was the only case of long duration in their series of 600 cases.

Olney<sup>6</sup> has seen several cases of prolonged paroxysmal auricular tachycardia in children, usually after infectious diseases. She states that the cases are usually benign and terminate spontaneously and are better left untreated if the heart is otherwise normal.

In adults, Hamilton and Hurwitz,<sup>7</sup> Herson and Willington,<sup>8</sup> Maddox<sup>9</sup> and Miller and Perelman<sup>10</sup> have reported cases. In reviews of large series of cases Gallavardin<sup>11</sup> found that 11 out of 160 patients had attacks lasting as long as ten days, 4 of these cases lasted over a month. None of the patients died during the attacks. Campbell<sup>12</sup> found 2 cases in his series of 100 that lasted longer than ten days. Hume<sup>13</sup> reported that only 1 of a series of 48 cases lasted over ten days. Levine<sup>14</sup> has followed a patient who had paroxysmal auricular tachycardia for twenty years, the auricular rate persisted at 240, and the ventricular rate was usually 120 but occasionally 60 or 240. Bouveret,<sup>15</sup> in the classic early article on paroxysmal auricular tachycardia, described a case lasting thirteen days.

## CASE REPORT

J. C., a 3-year-old boy, was first seen in the South Department of the Boston City Hospital for an acute pharyngitis and otitis. He received symptomatic treatment with prompt recovery. The heart rate and rhythm were normal at that time. He was next seen at the age of 5 on February 4, 1947, with a history of nasal discharge for 2 days and sore throat for 1 day.

There was no past history of any joint pains or palpitation. The family history was noncontributory, with no history of heart disease. The mother was 24 and the father 27 years of age, both were living and well. Four younger siblings were also living and well.

Physical examination disclosed a well developed and well nourished boy. There was a tonsillar membrane. The remainder of the examination was negative. The heart was not enlarged, the sounds were of good quality without murmurs, and the rate was 90 with normal rhythm.

The patient was given 30,000 units of diphtheria antitoxin intramuscularly. The nose and throat cultures proved positive for diphtheria bacilli. The membrane rapidly disappeared, and convalescence was uneventful. The patient received penicillin parenterally from March 11 to March 20 because of continued positive diphtheria cultures from the throat.

On March 18 the patient developed varicella. On April 3 the tachycardia was first noted. An electrocardiogram revealed a regular rate of 140 with inverted P waves in the limb leads. The pulse was regular, but the rate increased with emotion or exertion, it was unaltered by carotid sinus or eyeball pressure.

On April 11 the patient developed a moderate case of measles, without complications. Two days later an electrocardiogram revealed a rate of 94 with normal upright P waves except in Lead 4<sub>r</sub>, in which, after a deep breath, the rhythm changed from a paroxysmal tachycardia with upright P waves to a sinus rhythm with inverted P waves. Earlier that day and after the electrocardiogram the pulse had been 130 and regular.

\*Resident physician, South Department, Boston City Hospital.

On April 21 quinidine sulfate was given. Some irregularity of the pulse was noted after the third dose of 0.2 gm. An electrocardiogram revealed occasional runs of sinus rhythm interspersed in the paroxysmal auricular tachycardia. On the following day quinidine was given up to 1.2 gm without effect.

On April 23 digitoxin was started orally. Toxic symptoms were reached, and runs of normal sinus rhythm occurred but there was no prolonged conversion. About 3.5 mg was given in 4 days. On May 1 the patient was discharged and allowed full activity at home.

On May 12 0.2 gm of quinidine was given three times daily in addition to 1 teaspoonful of potassium acetate in 25 per cent solution three times daily. Because of vomiting of the potassium acetate potassium chloride solution was tried for 4 days but without effect.

From May 23 to June 20 the patient was given 0.1 mg of digitoxin daily and 0.2 gm of quinidine three times daily only to become toxic again without converting to sinus rhythm.

On June 24 the patient re-entered the hospital for esophageal electrocardiograms and a trial of mechoyl. Large doses of phenobarbital (up to 0.15 gm three times daily) over a week were first given in an attempt to obtain sedation. This therapy effected no appreciable degree of sedation nor did it alter the tachycardia. Sodium pentothal anesthesia, 1.2 gm by rectum was given on June 26 with prompt and effective anesthesia which enabled performance of esophageal lead electrocardiograms. On July 3 mechoyl was given for the first time, the technique described by Starr<sup>14</sup> being used. With the patient lying horizontal, alternate pressure over the carotid sinuses was tried when this was fruitless mechoyl was administered. The first dosage was 1.25 mg. When the tachycardia persisted after 3½ hour a larger dose (2.5 mg) was given. A third dose of 5 mg produced facial flush and sweating about 3 minutes after subcutaneous injection. The rhythm changed to a sinus tachycardia rate of 160 with

every 1½ hour. At 7.25 p.m. the pulse rate started to fall, from the preceding 136 to 114. By 8 p.m. the rate had reached 80 and the electrocardiogram revealed normal sinus rhythm with upright P waves (Fig. 2). The pulse rate remained below 100 until 10 o'clock the next morning when it started to rise. By 3.30 p.m. the pulse was 140 with the usual inverted P waves in the electrocardiogram. There was no effect on the blood pressure, which always remained around 110/70, nor were there any subjective symptoms. On July 23 at 4.30 p.m. the patient was given one tablet of veratris. Five hours later the pulse had fallen to 92, and the electrocardiogram showed upright P waves. At 7 o'clock the next morning the pulse rate had reverted to 140. The next

FIGURE 2. Electrocardiogram after the Administration of Veratris Showing Normal Sinus Rhythm in All Three Limb Leads

FIGURE 1. Electrocardiogram before the Administration of Veratris, Showing Paroxysmal Auricular Tachycardia in All Three Limb Leads

upright P waves in Leads 1, 2 and 3 then to a shifting pace maker for a minute and then back to the paroxysmal auricular tachycardia. On July 7 the patient was given 6.25 mg of mechoyl subcutaneously about 2 minutes later the rhythm switched from the tachycardia to a sinus rhythm at a rate of 80. He sweated, flushed, passed flatus, became nauseated and complained of abdominal pain. 0.0006 gm of atropine was given subcutaneously with prompt cessation of the side effects. The normal rhythm lasted about 10 minutes and then the tachycardia recurred.

The patient was next given a trial of veratrum viride. The first tablet of veratris\* (10 Crow units) was given on July 22 at 4.35 p.m. when an electrocardiogram disclosed paroxysmal auricular tachycardia in all three limb leads (Fig. 1). The pulse was checked every 10 minutes and the blood pressure

tablet of veratris on July 24 produced normal sinus rhythm for only 3½ hours. Another tablet of veratris that afternoon caused only a transient conversion to sinus rhythm with frequent changes from sinus rhythm to paroxysmal auricular tachycardia throughout the night. On July 25, 26, 27, 30 and 31 veratris was given — at first one tablet in the morning and one in the afternoon and then one tablet followed within 1 hour by another, there was no conversion to sinus rhythm.

On August 4 and 5 0.003 and 0.006 gm of pilocarpine were given without effect. On August 6 phystigmine (0.0006 gm) produced no effect later 0.0012 gm was given without effect. On the next day a blood pressure cuff was inflated about the patient's neck for about 20 seconds without response. On August 9 magnesium sulfate — 20 cc. in a 10 per cent solution — was given intravenously without producing a change. On August 11 one tablet of veratris was given at 9 a.m. and a second at 1.15 p.m., without effect.

Mechoyl in doses from 5 to 7.5 mg was given on August 18 and again on August 22 with a change in the rhythm to sinus tachycardia but no change to normal sinus rhythm. Each time the sinus tachycardia was soon replaced by the paroxysmal auricular tachycardia.

A tablet of veratris was tried again on October 5 without effect.

All the routine laboratory studies including blood studies (red-cell count, white-cell count, sedimentation rate and cholesterol), urinalyses and basal metabolic rate as well as x-ray films of the chest were normal.

The patient is now attending school without difficulty. The pulse continues to be rapid and regular.

#### DISCUSSION

The etiology of similar cases has been quite varied. Diphtheritic myocarditis usually occurs from the sixth to the twenty-first day after the onset of diphtheria.<sup>17</sup> It was the opinion that the case reported above probably did not represent a diph-

\*Kindly furnished by Inala, Neilsen and Company, Decatur, Illinois.

theritic myocarditis because of the late time relation and the lack of other signs or symptoms of myocarditis. In a series of 100 cases of severe diphtheria Begg<sup>18</sup> took routine electrocardiograms and found 1 case of paroxysmal auricular tachycardia. That case was fatal before the nineteenth day of the illness. Anderson<sup>19</sup> reported the case of a thirty-nine-year-old man who developed paroxysmal auricular tachycardia six weeks after a severe case of diphtheria and died within seventy-two hours of the onset of the tachycardia. In this case, however, it is probable that the patient had myocarditis much earlier.

Similar cases have been uniformly resistant to therapy. No reports in the literature state that veratrum viride has been used successfully in such a case. In a clinicopathological conference reported from the Massachusetts General Hospital<sup>20</sup> the unsuccessful use of the tincture of veratrum viride is mentioned. Collins<sup>21</sup> also reported the unsuccessful trial of veratrum viride tincture in a case of paroxysmal auricular tachycardia. The drug is not without danger and should only be used with a full knowledge of its toxic effects. The progressively diminishing response to veratrum, which probably represents tachyphylaxis, has been observed in dogs by Krayer and Acheson.<sup>22</sup>

Veratrum viride is obtained from the rhizome and roots of the plant *Veratrum viride*, commonly known as the green hellebore. It contains a mixture of alkaloids, the most important of which is protoveratrine. The main actions of veratrum are slowing of the heart rate, a fall in systemic blood pressure, slowing of the respiratory rate and a "collapse reaction" characterized by sweating and reduction in body temperature. Poisoning by the drug is characterized by nausea and vomiting, diarrhea, headache and cardiovascular collapse. Large doses of veratrum are rapidly vomited, however, so that death is rare. The site of action of the drug is believed to be the vagal nuclei in the medulla and the afferent nerve endings of the vagus nerve. Atropine will abolish the effects of veratrum and should be at hand in the event of an overdose.

### SUMMARY

A case of prolonged paroxysmal auricular tachycardia in a five-year-old boy two months after a moderate attack of diphtheria and two weeks after

an attack of varicella is presented. The paroxysmal tachycardia has persisted to date except for occasional, transient spontaneous conversion to normal sinus rhythm and has been temporarily converted to sinus rhythm by mecholyl and veratrum viride.

Digitalis, quinidine, potassium acetate, potassium chloride, physostigmine, pilocarpine, magnesium sulfate, carotid-sinus pressure, eyeball pressure, sedatives and a blood-pressure cuff inflated about the neck were without effect on the tachycardia. The patient has been asymptomatic throughout the duration of the tachycardia and is leading an active life. At no time has he shown any signs of cardiac enlargement or decompensation.

## FOOD SENSITIVITY IN 100 ASTHMATIC CHILDREN\*

LEWIS WEBB HILL, MD †

BOSTON

THAT food can cause asthma in children is a fact beyond dispute. The frequency of this sensitivity, as well as its relative importance to recurrent respiratory infection, sensitization to pollens and other environmental allergens, is an entirely different question, concerning which there is considerable difference of opinion.

An example of the way allergy is not infrequently treated is provided by the history of an asthmatic child of five years who was recently seen. She had previously been treated in another city and brought with her a typed list, bound in the form of a small book, of the foods that she could and could not eat, as determined by skin tests. The "good" foods were typed in black, and the "bad" foods in red, it was all very impressive. She had been tested with two hundred and thirty-six foods, including squab, tripe, calves' brain, venison, caviar, poppy seed, elderberry, pheasant, bops, chives and Limburger cheese, and had been found allergic to one hundred and nine of them, including Sanka coffee, rutabaga, German celery, thyme, cranberry, sand dab, tripe, sweetbreads and watercress. Among the foods she was allowed to eat were pheasant, guinea hen, venison, horse meat, turtle, abalone, terrapin, caraway seed, juniper, avocado, mango and quince. The asthma was in reality due to grass and tree pollen, and she was later quite successfully hypo-sensitized, with no dietary restrictions whatever.

This is by no means an isolated example. Too many people, without proper training or common sense, treat allergy in this way. Food allergy in particular lends itself to exploitation, for a dietary "cure" of any sort is a form of therapy that has made a great impression on the laity from time immemorial, and some of the greatest fads and mis-conceptions in medicine have had "diets" as their basis.

That sensitization to food is a common cause of allergic symptoms is certainly true, that too much pseudo-science and too little common sense are too often used in dealing with foods as allergens is equally true.

The general interest in diets as such, the tendency to attribute to the ingestion of foods all manner of complaints, the deep impression made by the occasional instance in the asthmatic of the sudden sharp often danger-ously severe attack following the eating of a specific food combine to give undue consequence to food allergy as a cause of asthma.<sup>1</sup>

To determine the influence of food upon asthma is by no means easy because there are so many

extraneous complicating factors involved, and no statistics can be really accurate.

For the purposes of this study, 100 asthmatic children between the ages of three and twelve years, partly from the clinic and partly from private practice, were observed and were tested by the scratch method. Thirty-five gave one or more positive tests to foods, and 65 gave none. There was no reason to believe that asthma was caused by food in any of those who gave negative tests; the asthma could be accounted for in other ways (such as animal emanations, pollens and upper respiratory infections). It is recognized, however, that asthma may be rarely caused by a food and that there may still be a negative skin test; the bronchial mucous membrane is sensitized, and the skin is not. In children this situation is believed to be rare, it is hardly ever necessary to employ elimination diets in the presence of negative skin tests to determine food sensitivity in the study of an asthmatic child. It is also recognized that an intracutaneous test to a food is often positive when the scratch test is negative. It was formerly the custom in this clinic to do routine intracutaneous tests with foods in all the asthmatic children. There were so many positive reactions that meant nothing clinically and it was so rare to obtain any information of value that this procedure was given up. Intracutaneous tests with environmental allergens, particularly with pollens, when scratch tests are negative, are, however, of great value, and when positive usually indicate clinical sensitivity.

Very few of the children in this series had continuous asthma—in almost all there were periods of at least three or four weeks when they were free from it. If they were eating the foods in question daily or frequently during these periods and no asthma was produced, it was concluded that the foods were harmless so far as asthma was concerned. If the child was having nearly continuous asthma, the reacting foods were removed from the diet and reintroduced one at a time during asthma-free periods, and the results noted. If there was any suspicion of a food that was eaten infrequently, this was given in ordinary amounts, and if no asthma occurred within forty-eight hours, it was concluded that the food in question had nothing to do with the asthma. There were a few cases of very large skin reactions to fish or nuts in which this test was not done, since I did not wish to run the risk of producing a dangerous reaction with these potent allergens. The food question was discussed frequently and for considerable periods with the mothers, for most of the children were being brought

\*From the Allergy Clinic, Children's Hospital, and the Department of Pediatrics, Harvard Medical School.

†Associate in pediatrics, Harvard Medical School, visiting physician and chief of Allergy Clinic, Children's Hospital.

in for inoculations each week. It was almost always found that the mother knew from previous experience what foods produced asthma.

In 24 of the 100 children studied asthmatic attacks had been or could be produced by the ingestion of a specific food. In most cases this had been recognized by the mother before the child was seen, and the food or foods in question had been removed from the diet, so that there were not many cases in which food was concerned in producing the asthma at the time the child was brought in.

In the 100 children there were 218 positive scratch tests to foods (Table 1). Of these, there were 44

in 2. No symptoms were caused by one hundred and fifty-eight foods (72 per cent) to which tests showed skin sensitivity. It is probably true that asthma would have been produced in some of these patients had a considerable amount of the food been ingested. Not uncommonly, however, the degree of sensitivity to some of these foods, such as fish and nuts, is so high that as soon as any of the food touches the lips or enters the mouth, the mucous membrane begins to swell, and the food is immediately spat out or regurgitated before there has been any chance for it to be absorbed. If these cases are included, the number of foods producing asthma is increased from forty-four to sixty.

### DISCUSSION

These figures agree with those of Adams<sup>2</sup> and of Chobot and Hurwitz.<sup>3</sup> Adams found that of 130 positive scratch tests to foods in a group of allergic children, 23 per cent were of clinical significance. Chobot and Hurwitz observed that 18 per cent of 198 positive scratch tests to foods in 38 allergic children were of clinical significance.

It seems well established, therefore, that only about a fifth of the positive scratch tests to foods in asthmatic children have anything to do with the asthma, and furthermore that, although it is possible for clinical sensitivity to any food to exist in these children and to be at least a contributing factor to the asthma, the number of foods that cause such sensitivity with any frequency is not large (fish, egg, nut, peanut and chocolate), as a rule, a high degree of sensitivity must exist for a food to cause asthmatic attacks. Wheat and milk, which may be of considerable importance in the atopic dermatitis of infants and in many other allergic conditions, rarely caused asthma in the children under consideration, and positive scratch tests were not common (Table 1).

In asthma, positive skin tests to environmental allergens are usually of etiologic significance; the mucous membrane of the respiratory tract, as well as the skin, becomes easily sensitized to these allergens. To cause a positive skin test to a food, unsplit food protein must at some time have entered the blood stream, and in atopic people an immunologic reaction results, which is manifested by a positive skin test. The respiratory mucous membrane is likely to escape sensitization, the immunologic reaction is shown only on the skin, and possibly by the presence of reagins in the blood serum. Positive tests to foods have the same significance as positive tuberculin, trichophyton or brucella tests: at some time the organism has been exposed to antigenic material, and an immunologic reaction, which may or may not have anything to do with the clinical condition under consideration, has occurred. One would expect, however, that if there were a high degree of skin sensitivity, as in many of the nonetiologic tests, if the food were eaten,

TABLE 1 *Results of Skin Tests to Foods in 100 Asthmatic Children*

\*No asthma caused by foods in these cases.

(20 per cent) in which it was definitely proved that the food in question could cause asthma. It is especially noteworthy that egg white, fish, peanut, walnut and chocolate accounted for 38 of the 44 etiologic tests. The other foods producing asthma were tomato in 2 cases, spinach in 1, orange in 1, corn in 1 and barley in 1. Although potato gave 22 positive tests (some of them large wheals with pseudopods), in no case could it be shown that the ingestion of potato produced asthma or any other symptom. Since the first days of skin testing, spinach extracts have always been nonspecifically irritating, and it is probable that a large proportion of the positive tests to spinach were of this character. It did cause asthma in 1 patient, however. In 16 cases (8 per cent) a food that gave a positive test caused irritation about the mouth, vomiting, urticaria or angioneurotic edema, but no asthma. This was true of asparagus and banana in 1 case each, egg white in 4, fish in 2, orange and peanut in 1 each, spinach in 2 and walnut

dermatitis or urticaria would result, inasmuch as the skin is sensitized. Nevertheless, in 218 cases of positive tests in the series of children under discussion, the corresponding food could be eaten with complete impunity in 158—there was no asthma, urticaria or eczema, in spite of the fact that in many of these patients the skin showed a high degree of sensitization.

Some of the positive tests had been of etiologic significance when the child was younger, and with increasing age he had become "tolerant" to the food, some of them had never been of etiologic significance. There is a great tendency in allergic children to acquire tolerance to foods as they grow older. Many children who have violent symptoms from egg white at the age of a year, can eat it with impunity at the age of six years, but the positive skin test often persists, and the reaction may be as large as it was in the beginning. Tolerance to environmental allergens does not come so readily; the child clinically sensitive to cat hair or to ragweed pollen is likely to remain sensitive for a long time, often through life.

The immunologic situation in these children who are tolerant to foods in the presence of large positive skin reactions, and who often have reagins of high titer as well, is not clearly understood, nor is the mechanism by which they acquire this tolerance. If absorbed food protein reaches the skin, urticaria or dermatitis should result. Therefore, either unsplit food protein is not absorbed in sufficient quantity to cause a reaction, or some mechanism has been developed by which it is rendered innocuous after it has been absorbed. It must be remembered, however, that a very high degree of skin sensitivity must be present before urticaria can result from an ingested food, and that the solutions used by outside application or intracutaneous introduction in testing, which produce whealing reactions, are probably many times more concentrated than the concentration of a small amount of absorbed food protein when it has been diluted in the several liters of blood contained in the body. If the degree of skin sensitivity is very high, however, an infinitesimal amount of absorbed allergen may cause whealing. Brunner and Baron<sup>4</sup> found, for example, that the intravenous administration of cottonseed extract containing 0.0001 mg of nitrogen caused an urticarial reaction on skin sites that had been artificially sensitized with a serum containing a high titer of cottonseed reagin. When diluted with the amount of blood plasma contained in an adult (approximately 3000 cc.), this would mean a dilution of 1:30,000,000. Walzer<sup>5</sup> found that 0.0001 mg of nitrogen represented 1/5600 of one cottonseed. So that with a very high degree of skin sensitization it is necessary for only traces of food protein to be absorbed to cause urticaria.

It is a fact that any food protein can be absorbed unsplit—if this were not so there would be no

positive skin tests to foods. It is also a fact that this absorption can happen at any age and probably true that there is a considerable difference in the ease with which various food proteins are absorbed—for example, fish, nut and egg protein are consistently absorbed by many people. Not much is known about other foods, however, and it is not unlikely that with many people the unsplit protein of many foods is absorbed only for a short time when the food is first eaten, enough for the development of an immunologic reaction, evidenced by a positive skin test—no more after that, or at any rate not enough to cause a reaction except possibly if an excessive amount of the food is eaten. Some people, however, seem to absorb the unsplit protein of a number of foods over long periods; if this were not so there would be no asthma from food, no dermatitis, no urticaria and no migraine. It seems likely that there is a great individual variability in this respect.

If unsplit food protein reaches the skin in sufficient amount and the skin is strongly sensitized, some skin manifestation should result. Therefore if no reaction takes place, the protein has not been absorbed in sufficient amount, or at all, or it has been changed after absorption in some way so that it is no longer antigenic.

In asthma the situation is somewhat different, for the bronchial mucous membrane may not be sensitized. If it is sensitized, the situation in asthma may be compared to that in dermatitis: either failure of sufficient absorption or neutralization after absorption.

## CONCLUSIONS

About a fifth of positive scratch tests to foods in asthmatic children are of etiologic significance.

The mother usually knows what food produces asthma, and has omitted it before skin tests are done.

Theoretically, any food can cause asthma, practically, not many foods commonly do so. Fish, egg, walnuts, peanuts and chocolate are the most important. Wheat and milk can cause asthma in children, but do not often do so.

Sensitivity to food, which should always be taken into consideration in asthmatic children, is of relatively little importance in comparison with sensitivity to pollen, other environmental allergens and upper respiratory infections.

## GENERALIZED EXFOLIATIVE DERMATITIS DUE TO PENICILLIN\*

CAPTAIN J. ORDIE SHAFFER, M.C., A.U.S.

THE increasing frequency of reactions to penicillin warrants wider recognition of the dangers of the local application of penicillin, and more reliance placed on less sensitizing methods of administration, such as the intramuscular, intravenous and intra-arterial routes<sup>1,2</sup>. Although the direct toxic action of penicillin is negligible,<sup>3</sup> aside from the irritating effect when the drug is applied to the central nervous system,<sup>4</sup> the delayed or acquired sensitivity reactions may be severe or fatal. Wile<sup>5</sup> noted that severe allergic reactions involving edema of the pharynx, larynx and lungs complicating penicillin therapy are serious and may result in fatal complications. Numerous other authors have reported severe reactions simulating asthma,<sup>6</sup> serum sickness<sup>7,8</sup> and epidermal reactions such as bullous dermatitis.<sup>9</sup> Kolodny and Denhoff<sup>10</sup> have stated that patients with dermatologic disorders have a higher sensitivity than other patients. Gottschalk and Weiss<sup>11</sup> noted that a delayed or acquired sensitivity could be produced by repeated local applications of penicillin. By using a simple patch test they were able to sensitize 4.5 per cent of 200 persons to penicillin ointment. Pillsbury<sup>12</sup> states that the incidence of sensitivity reactions at present is over 15 per cent, and he believes that this percentage may increase as the incidence of exposure to penicillin is increased. The fact that these reactions are not limited to local manifestations but that severe generalized eruptions occur often escapes due consideration. Cormia<sup>13</sup> noted severe systemic involvement in patients after the local application of penicillin, and Barksdale<sup>14</sup> reported a fatal case of exfoliative dermatitis due to penicillin therapy. Barksdale's patient did not have syphilis and had become sensitized to penicillin therapy while at sea. He was also sensitive to sulfonamides. He was given 100 units of penicillin every three hours, for a cellulitis of the skin, but at the end of the seventh dose the administration of penicillin had to be discontinued because of a severe cutaneous eruption, which progressed into a generalized exfoliative dermatitis, streptococcal septicemia and death. Because of this and other toxic reactions complicating the use of penicillin locally for the treatment of skin diseases, Barksdale concludes that "penicillin locally in any form is absolutely contraindicated." The following case is reported as further evidence that complications dangerous to life may result from the local use of penicillin.

## CASE REPORT

A 27-year-old man with no history of allergic disorders or previous penicillin therapy, was seen in the outpatient clinic of an Army hospital ship on November 14, 1946.

\*The opinions and views set forth in this article are those of the writer and are not to be considered as reflecting the policies of the Army Medical Department.

Physical examination disclosed typical impetigo contagiosa of the skin, with honey-like crusted lesions on an erythematous base on the left side of the neck.

The patient was instructed to wipe the area twice daily with alcohol and after this had dried to apply penicillin ointment in a petrolatum base (1000 units per cubic centimeter) locally. The lesions retrogressed and the patient improved during the first 3 days of therapy, but on the 4th day coalescing vesicular lesions covered with a honey-like material on an erythematous base spread further on the left cervical region and appeared at the right angle of the mouth. He was admitted to the hospital, and local therapy was continued with penicillin ointment. Two days later the individual lesions had improved, but an erythematous lesion had appeared involving the skin more deeply and covering the entire area over which the ointment had been applied. This sharply demarcated area was erythematous, edematous and indurated, and there was an increase in local temperature. There was no systemic toxicity, however, to suggest a true erysipelas. Local penicillin therapy was discontinued, and Burrows boric acid wet soaks were given as the only treatment. On the following day the erythematous lesions had spread further on the neck so that 30,000 units of penicillin every 3 hours was started intramuscularly in addition to the local wet compresses. No improvement of the local lesions resulted, and on November 22 severe pruritus of the involved area occurred. On November 23 a fine maculopapular generalized eruption was noted with a more erythematous reaction over the scrotum and inner aspects of the thighs. A diagnosis of dermatitis medicamentosa was made, and the intramuscular administration of penicillin was discontinued immediately. Phenolated zinc lotion was used to control the intense associated pruritus. The skin lesions deepened in color, and within the next 7 days a generalized exfoliative reaction of the entire body, including the palms, soles, scalp and eyelids, occurred.

The patient subsequently had no difficulty, but he was cautioned against receiving penicillin in any form again. An interesting therapeutic note was that the impetigo of the face and neck never disappeared on either local or intramuscular administration of penicillin, but disappeared after 5 days of therapy with ammoniated mercury ointment.

## DISCUSSION

This case demonstrates that systemic sensitization to local applications of penicillin may rapidly occur so that severe generalized reactions are not prevented by a change to parenterally administered penicillin. The potential dangers of penicillin applied locally more than offset any advantages of this mode of therapy. Generalized exfoliative dermatitis is a complication to be feared and should not be risked by the local application of penicillin ointment to an innocuous skin lesion. In the case reported above continuation of intramuscular penicillin after the occurrence of the generalized rash might have caused a fatality. The occurrence of localized exfoliative dermatitis in other cases has emphatically illustrated the dangers of local penicillin. One patient had an exfoliation of the skin of the entire external ear canal and pinna, after treatment of a chronic suppurative otitis media, with purulent drainage from a tympanic perforation by installation of penicillin solution into the ear. The impression gained from personal experience is that the local administration of penicillin in the region of the head and neck causes a higher rate of sensitization and is definitely contraindicated. With

the possibility of severe and potentially fatal reactions and the chance that sensitivity induced by local therapy may prevent parenteral penicillin therapy when a severe systemic infection later occurs, it seems best to discontinue local penicillin therapy entirely. The availability of other suitable local therapeutic agents, such as ammoniated mercury and tyrothricin, and the superiority or equality of parenterally administered penicillin in the treatment of superficial cutaneous infections are further facts to discourage the dangerous practice of using penicillin locally.

### SUMMARY

A case of generalized exfoliative dermatitis due to sensitivity to penicillin is presented.

Penicillin ointment is contraindicated in the treatment of skin lesions because of the reactions dangerous to life that may occur during the treatment of an innocuous condition and also because systemic sensitization may prevent later parenteral use of

penicillin when it is needed to combat a severe systemic infection.

## MEDICAL PROGRESS

### REGIONAL ANESTHESIA\*

JOSEPH M. DONDANVILLE, M.D.,† AND MORRIS J. NICHOLSON, M.D.‡

BOSTON

THE war and the following years witnessed a widespread increase of interest in regional anesthesia. This was a natural sequence to the emphasis placed upon the role of anesthesia in war surgery. Many of the young physicians who received training in anesthesiology during the war have chosen to complete their training in that specialty. Their enthusiasm has added to the magnitude of experimental and clinical investigation of the postwar period. Differential spinal block has furnished new evidence of the mechanism of nerve block. New diagnostic and therapeutic sympathetic blocks have broadened the field of the anesthesiologist. Segmental spinal anesthesia invites further investigation into the potentialities of decreasing the concentration of a spinal anesthetic agent. The synthesis of morphine-like compounds promises a brighter future for better premedication and post-operative relief of pain. The development of new and the modification of older techniques in the past few years have aided in the personalization of the anesthesia to the individual patient.

### DIFFERENTIAL SPINAL BLOCK

It has long been known that anesthetic agents introduced into the subarachnoid space did not equally affect all nerve components. New evidence that the smaller, nonmyelinated fibers are blocked first is presented in the work of Sarnoff and Arrowood<sup>1-3</sup> on "differential spinal block." They employed the continuous spinal technic with 0.2 per cent procaine hydrochloride solution in an attempt to produce differential block of the sympathetic fibers. Skin-temperature readings were used as a measure of sympathetic activity. Their results indicated that sympathetic preganglionic vasomotor and adrenergic fibers were blocked at or about the same time as the fibers concerned with the appreciation of pinprick. These fibers were blocked without impairment of the modalities of touch, deep pressure, position sense or vibratory sense and with no loss of motor power. A further observation was that position sense and the stretch reflexes are mediated by separate groups of fibers. This was shown by a loss of abdominal, patellar and Achilles-tendon reflexes when position sense was still appreciable.

\*From the Department of Anesthesiology, Lahey Clinic.  
†Fellow in anesthesiology, Lahey Clinic.  
‡Member, Department of Anesthesiology, Lahey Clinic.

Jackson<sup>40</sup> described another aliphatic amine similar to oenethyl except for an extra methyl and hydroxyl radical. This drug, termed EA-83, is readily absorbed from the gastrointestinal tract in dogs, but as yet no clinical investigation has been undertaken.

### *Morphine and Morphine-like Drugs*

Drew, Dripps and Comroe<sup>41</sup> studied the effects of morphine upon the circulatory changes in man after position change. They found that movement of a "morphinized" patient from the supine to the sitting or semierect position may be followed by vascular collapse. Powers<sup>42</sup> re-emphasized the addiction properties of demerol, and Robbins<sup>43</sup> demonstrated that cyclopropane-induced cardiac irregularities after morphine premedication are not seen in the dog when demerol is used. Foster and Carman<sup>44</sup> tested demerol and other piperidine derivatives on the rat and reported that some are deserving of clinical trial.

When the United States Government study commissions went to Germany after World War II, they found a group of compounds, prepared by German chemists, that exhibited hypnotic action. One of these synthetic hypnotics — No. 10820, or dolophine — has been thoroughly studied by the Lilly research group and named methadon (6-dimethylamino-4,4-diphenyl-heptanone-3). C. C. Scott and Chen<sup>45-47</sup> found that methadon has an analgesic effect as powerful as morphine. In addition, it depressed respiration, caused cardiac slowing and produced a slight to moderate fall in blood pressure, but there was no depression of salivary secretion and it only occasionally caused nausea and vomiting. An associated depression of the cough reflex and parasympathomimetic stimulation of the small bowel were noted. Isbell<sup>48</sup> used methadon in the treatment of morphine addiction and reported the development of tolerance and addiction to methadon. With methadon, however, withdrawal symptoms were not nearly so severe as those with morphine, and he advocated substitution of methadon for morphine before withdrawal in addicts. W. W. Scott et al.<sup>49</sup> observed no euphoria when methadon was given clinically for preanesthetic medication and postoperative relief of pain.

### *Local Anesthetic Agents*

An increasing number of compounds are being investigated from the standpoint of their potential anesthetic properties. Krop<sup>50</sup> studied pyridium ( $\beta$ -phenylazo  $\alpha$ - $\alpha'$  diamino pyridine monohydrochloride) and re-emphasized that it might be useful as a topical anesthetic in the bladder and urethra. Kuna and Seeler<sup>51</sup> studied the anesthetic properties of a large group of alkyl amino alcohol esters and reported that several hold promise for infiltration anesthesia. One in particular in this group, 2-cyclopentyl amino-1-propyl p-aminobenzoate hydrochloride, might prove valuable for topical as well as for

infiltration anesthesia. Ramsey and Haag<sup>52</sup> reported a series of aryl-urethanes that possessed anesthetic activity greater than that of cocaine when instilled in the rabbit eye.

Combes et al.<sup>53</sup> advocated the use of topical anesthetic agents in ointment bases for the treatment of burns and cutaneous ulcers. They claimed that this procedure promoted rapid healing and soft scar formation by lessening the vasodilatation, edema and muscle spasm that accompanies the pain of the acute lesion.

### OBSTETRIC ANESTHESIA

Spinal analgesia for obstetric delivery is enjoying greater popularity than ever before. Weaver and his co-workers,<sup>54</sup> Turner<sup>55</sup> and Marcus and his associates<sup>56</sup> reported on large series with excellent results. Cullen and Griffith<sup>57</sup> compared post-partum results of spinal and gas anesthesia for vaginal delivery. The evidence in their study was in favor of spinal anesthesia, except that headaches were severer, although the incidence of headache in the two groups was the same. Weintraub et al.<sup>58</sup> compared the incidence of postlaparotomy spinal headache in cesarean section and various gynecologic operations with the incidence in vaginal delivery under spinal anesthesia. The incidence of headache following spinal anesthesia was much higher in the last group than in the first two groups, averaging 15 per cent in 300 patients. In the vaginal-delivery group 50 per cent of the patients who complained of headache exhibited orthostatic hypotension or tachycardia or both. These investigators found that the application of a tight abdominal binder post partum gave complete or almost complete relief in 90 per cent of the patients with headache.

Resnick,<sup>59</sup> of Great Britain, weighted nupercaine with glucose for use in obstetric delivery. Parmley and Adriani,<sup>60</sup> in this country, popularized "saddle block" anesthesia with heavy nupercaine for vaginal delivery.

Caudal and continuous caudal anesthesia are still enjoying great popularity in certain communities. Brown et al.<sup>61</sup> tested various concentrations of pontocaine in physiologic saline solution with epinephrine (dilution of 1:200,000) for duration of effect. Using continuous caudal anesthesia, they found that pontocaine, 0.15 per cent, proved the most effective.

A review of the technic of pudendal-nerve block is reported by Eisaman and McHenry.<sup>62</sup>

### TECHNICS

The increasing number of qualified anesthesiologists has brought reports of new technics in regional anesthesia. Adriani and Roman-Vega<sup>63</sup> used saddle-block anesthesia with a weighted solution of nupercaine. They employed the sitting position for injection and produced anesthesia in the anoperineal region without motor block of the lower extremities.

A method of continuous brachial-plexus block utilizing a blunt needle with a cork stabilizer was presented by Ansbro<sup>41</sup>. Kersbner and Shapiro<sup>42</sup> reported a technic of interlaminar approach for spinal subarachnoid puncture as an alternative to the conventional interspinous method.

Lund and Rumball<sup>43</sup> dissolved pontocaine crystals in distilled water to make a 0.1 per cent hypobasic solution in a controlled series and concluded that the ephedrine decreased the dosage by approximately a third but did not appreciably increase the length of its effect. Ruben<sup>44</sup> added ephedrine to pontocaine-glucose and made use of the prolonged lateral position to obtain increased length of anesthesia for unilateral orthopedic procedures on the lower extremity.

Roman-Vega and Adriani<sup>45</sup> reported further on the use of weighted nupercaine with gravity control for general abdominal surgery. Nitikman<sup>46</sup> outlined another formula for nupercaine dosage in nucleopulposus surgery.

Two articles on the status of epidural anesthesia are in the recent literature, both from the southern continents where this technic apparently enjoys much greater popularity than it does in this country. Lima<sup>47</sup> reported from Brazil, and van Hoogstraten<sup>48</sup> from the Union of South Africa.

McCann<sup>49-51</sup> has made use of supplementary nerve block with pentothal sodium anesthesia for general surgery. Relaxation for abdominal surgery was achieved by transincisional blocking of the intercostal nerves within the rectus sheath. He prevented deep reflex stimulation of respiration by anterior splanchnic and mesenteric block in intra-abdominal surgical procedures. Transincisional intercostal block was done during radical mastectomies. The quantity of pentothal necessary for any general surgical operation was reduced by almost 50 per cent when such supplementary nerve block was employed.
